

**Simulation of Jet D'Eau from A to Y:
Numerical algorithm to solve incompressible Navier-Stokes
equations with marker and cell based method**

Pablo Strasser

Master thesis under the supervision of
Prof. Martin Gander and Dr. Felix Kwok

Abstract

We will in this work present how to solve Navier-Stokes equations with a marker and cell method. We use direct Navier-Stokes approach without other model than the Navier-Stokes equations. We emphasize the mathematical modularity which allow to work separately on every piece of this work. Our method work for every Runge-Kutta method (explicit or implicit), if we note k the order of the chosen Runge-Kutta method, our method is of order k if we ignore boundary conditions, of order k at the better case and of order 1 for specific complicated case. Our method is exactly divergence free (at numerical precision).

We will specially be interested in free surface boundary conditions. The final goal is to solve a Jet d'Eau. This goal was only partially achieved, but the needed basics are there.

Introduction

This work consists of the following chapters:

1. A notation and basic math property chapter.
2. A chapter that describe the problem analytically. In this chapter no discretization is done, but equations are written in the good form to motivate discretization.
3. A chapter that is interested on the solution of Navier-Stokes equations if the domain of computation is fixed.
4. A chapter that indicate the change needed to allow domain change.
5. To end, a conclusion chapter which will contain pist to upgrade the scheme used.

The two numerical chapters contain pseudo code that implement the described algorithm.

The original **C++11** code can be found on <https://github.com/Strasser-Pablo/Mac> but is not needed to understand this work, the pseudo code is sufficient.

All the chapters are self contained, but further information and inspiration come from:

- Algorithmic idea like the layer variable and the first scheme come from [?].
- Analytical comprehension and better formulation come from [?].
- Extrapolation for boundary conditions come from [?].
- Analytical solution are taken from [?] and [?].
- A review of marker and cell based method can be found in [?].

Chapter 1

Notation and basic property

Contents

1.1 Vector	7
1.2 Differential operator	7
1.3 Divergence free and rotational free space	8
1.4 Projection	8

1.1 Vector

We denote vector with the dimension of physical space (2d or 3d) \mathbf{v} . We only use Cartesian coordinate system. We indicate a given component of a vector with indices. v_1 indice the first component.

1.2 Differential operator

We denote derivative ∂_i where i is the spatial component with which we derivate.

$$\partial_i v(\mathbf{x}) = \frac{\partial v(\mathbf{x})}{\partial \mathbf{x}_i} \quad (1.1)$$

Definition 1.2.1 (Nabla). *In Cartesian coordinate, the ∇ is a vector that cannot commute. Its expression is given by:*

$$\nabla_i = \partial_i \quad (1.2)$$

With the ∇ we can form the following expression. With n the dimension of the vector:

$$\nabla p = \begin{pmatrix} \partial_1 p \\ \vdots \\ \partial_n p \end{pmatrix} \quad (1.3)$$

$$\nabla \cdot \mathbf{v} = \sum_{i=1}^n \partial_i \mathbf{v}_i \quad (1.4)$$

$$((\mathbf{v} \cdot \nabla) \mathbf{v})_i = \sum_{j=1}^n v_j \partial_j v_i \quad (1.5)$$

Definition 1.2.2 (Laplacian). *The Laplacian Δ consists of a scalar operator:*

$$\Delta p = \nabla \cdot \nabla p = \sum_{i=1}^n \partial_i \partial_i p \quad (1.6)$$

Definition 1.2.3 (Vector Laplacian). *A vector version of the Laplacian consists to apply the Laplacian to all component of the vector.*

$$\Delta \mathbf{v} = \begin{pmatrix} \Delta v_1 \\ \vdots \\ \Delta v_n \end{pmatrix} \quad (1.7)$$

1.3 Divergence free and rotational free space

Definition 1.3.1 (Divergence). *The divergence of a vector consists of:*

$$\nabla \cdot \mathbf{v} \quad (1.8)$$

Definition 1.3.2 (Rotational). *The rotational of a vector consists of:*

$$\nabla \times \mathbf{v} \quad (1.9)$$

Definition 1.3.3 (Gradient). *The gradient of a scalar consists of:*

$$\nabla p \quad (1.10)$$

Property 1. *The gradient is rotational free.*

$$\nabla \times \nabla p = \mathbf{0} \quad (1.11)$$

Property 2. *The rotational is divergence free.*

$$\nabla \cdot \nabla \times \mathbf{v} = 0 \quad (1.12)$$

1.4 Projection

Property 3 (Projection of a divergence free space). *Every vector can be projected to a divergence free space without changing its rotational with the following change:*

$$\mathbf{v}_{\text{new}} = \mathbf{v} - \nabla p \quad (1.13)$$

$$\Delta p = \nabla \cdot \nabla p \quad (1.14)$$

Proof Taking the divergence of equation 1.13 and using 1.14

$$\mathbf{v}_{\text{new}} = \nabla \cdot \mathbf{v} - \Delta p = \nabla \cdot \mathbf{v} - \nabla \cdot \nabla p = 0 \quad (1.15)$$

■

Remark 1.4.1. *This work as long as:*

$$\Delta = \nabla \cdot \nabla \quad (1.16)$$

So this can be used in discretized case and will be exact as long as 1.16 is respected.

Definition 1.4.1 (Linear projection operator). *We define the projection operator $P(\mathbf{v})$*

$$P(\mathbf{v}) = -\nabla \Delta^{-1} \nabla \cdot \mathbf{v} \quad (1.17)$$

The projection of section 1.4 is then written:

$$\mathbf{v}_{new} = \mathbf{v} + P(\mathbf{v}) \quad (1.18)$$

In case where we use boundary conditions that are not 0 Dirichlet or Neumann boundary condition. The projection operator is no more linear, but affine.

Definition 1.4.2 (Affine projection operator). *We denote affine projection by $P(v, T) = Av + T$.*

The Poisson's equation is given by:

$$\Delta p = \nabla \cdot v \quad (1.19)$$

This can be rewritten for Dirchlet or Neumann boundary conditions:

$$Bp = \nabla \cdot v - c \quad (1.20)$$

Where B is a matrix form of Δ which depend only on quantity of the domain. Where c is given by the boundary conditions. p is then given by:

$$p = B^{-1} \nabla \cdot v - B^{-1} c \quad (1.21)$$

And the projection is:

$$P(v, T) = -\nabla p = -\nabla B^{-1} \nabla \cdot v + \nabla B^{-1} c \quad (1.22)$$

Which can be rewritten:

$$P(v, T) = Av + T \quad (1.23)$$

$$A = \nabla B^{-1} \nabla \cdot \quad (1.24)$$

$$T = \nabla B^{-1} c \quad (1.25)$$

The important change is that the projection of a divergence free vector field is no more 0.

$$P(v, T) = Av + T = 0 + T = T \quad (1.26)$$

Introduction

In this chapter, we will discuss the analytical problem that we want to solve. The other numerical chapters will consist of numerical schemes to solve the problem given in this chapter.

2.1 Variables and parameters

The problem will consist to find a function of space and time in a certain domain respecting some conditions and equations.

We begin to define space, time and domain:

The *space* consists of a vector in fixed Cartesian coordinate with dimension typically 2 or 3 (Navier-Stokes on 1d is trivial). Space is noted \mathbf{x} .

The *time* consists of a indice indicating the evolution of the function in time. Time is noted t .

The *domain* is the spatial region where a field is defined. This consists physically in the spatial region where water lies. Boundary conditions need to be provided. The domain can vary with respect of time and can vary with respect of the solution at previous time. The domain doesn't need to be connected. But can be decomposed in union of connected subdomain.

Example 2.1.1. If we take a drop of water falling in a glass of water. The domain consist of the region where the water lies. At the beginning this will consist of domain consisting of two connected subdomains (the drop and the glass) that after a given time will merge in one domain.

The domain is generally noted Ω or $\Omega(t)$ to emphasize that it can be variable with respect of time.

The variable of the equation are named *Field* and consists of functions with respect of space in the spatial domain and time in the temporal domain.

$$F(x, t) \quad \text{With } x \in \Omega(t) \text{ and } t_0 \leq t \leq t_f \quad (2.1)$$

We have the following fields:

The speed: A vector field consisting of the speed in space and time. The speed is noted \mathbf{v} .

The pressure: A scalar field consisting of an internal force per unit area in the fluid.

We will not use the pressure in this work, but the pressure divided by density. If we note the pressure \tilde{p} we use:

$$p = \frac{\tilde{p}}{\rho} \quad (2.2)$$

Because we use incompressible Navier-Stokes equation, ρ is constant. This can be view as a change of unit.

The following constant parameters are used:

The viscosity represents how much water particles stick together. Higher is the viscosity less abrupt speed changes are possible. The viscosity is noted μ . We use allot ν that is the viscosity divided by the density.

$$\nu = \frac{\mu}{\rho} \quad (2.3)$$

The density is a mass per unit volume. Density play the same role as mass in Newton's mechanic. In the incompressible Navier-Stokes equation density is a constant because incompressibility tells us that density doesn't change. The density is noted ρ .

The external force is a user defined vector field that represents the external force applied to the water. It can possibly depends on the solution for previous time. The force is noted \mathbf{F} .

2.2 Navier-Stokes equations

2.2.1 Fixed eulerian topology

The incompressible Navier-Stokes equations are given by:

$$\nabla \cdot \mathbf{v}(\mathbf{x}, t) = 0 \quad (2.4a)$$

$$\partial_t \mathbf{v}(\mathbf{x}, t) + (\mathbf{v}(\mathbf{x}, t) \cdot \nabla) \mathbf{v}(\mathbf{x}, t) = -\nabla p(\mathbf{x}, t) + \frac{\mathbf{F}(\mathbf{x}, t)}{\rho(\mathbf{x}, t)} + \nu \Delta \mathbf{u}(\mathbf{x}, t) \quad (2.4b)$$

Equation 2.4a, tells us that the speed is a divergence free field. Equation 2.4b is an equation of evolution. The presence of p allows to maintain the speed always divergence free. Taking the rotational of 2.4b make disappear the pressure term (because the rotational of a gradient is 0).

The pressure term can be seen as a correction of the divergence without changing the rotational.

We can rewrite Navier-Stokes equations as:

$$\nabla \cdot \mathbf{v}(\mathbf{x}, t) = 0 \quad (2.5a)$$

$$\partial_t \mathbf{v}(\mathbf{x}, t) = f(\mathbf{v}(\mathbf{x}, t)) - \nabla p \quad (2.5b)$$

Where

$$f(\mathbf{v}(\mathbf{x}, t)) = -(\mathbf{v}(\mathbf{x}, t) \cdot \nabla) \mathbf{v}(\mathbf{x}, t) + \frac{\mathbf{F}(\mathbf{x}, t)}{\rho(\mathbf{x}, t)} + \nu \Delta \mathbf{u}(\mathbf{x}, t) \quad (2.5c)$$

Taking the divergence of equation 2.5b we found:

$$\Delta p = \nabla \cdot f(\mathbf{v}) \quad (2.6)$$

But using the notation of 1.4.1:

$$-\nabla p = P(f(\mathbf{v})) \quad (2.7)$$

The equations of Navier-Stokes are then equivalent to solve:

$$\partial_t \mathbf{v}(\mathbf{x}, t) = f(\mathbf{v}(\mathbf{x}, t)) + P(f(\mathbf{v}(\mathbf{x}, t))) = (1 + P)f(\mathbf{v}(\mathbf{x}, t)) \quad (2.8)$$

$(1 + P)$ is a projector on a divergence free space without changing the rotational.

2.2.2 Mobile eulerian topology

When topology is variable, we need to add another equation to tell where is the domain of computation. A natural boundary condition is the free surface, which moves with the speed at given point.

We define λ a system of representative. And ξ_λ the position of point given by λ . The domain is given by the union of ξ for all λ .

The Navier-Stokes equations are now:

$$\nabla \cdot \mathbf{v}(\mathbf{x}, t) = 0 \quad (2.9a)$$

$$\partial_t \mathbf{v}(\mathbf{x}, t) + (\mathbf{v}(\mathbf{x}, t) \cdot \nabla) \mathbf{v}(\mathbf{x}, t) = -\nabla p(\mathbf{x}, t) + \frac{\mathbf{F}(\mathbf{x}, t)}{\rho(\mathbf{x}, t)} + \nu \Delta \mathbf{u}(\mathbf{x}, t) \quad (2.9b)$$

$$\partial_t \xi_\lambda(t) = \mathbf{v}(\xi_\lambda, t) \quad (2.9c)$$

We can as in section 2.2.1 eliminate the constrain on the divergence with the same notation:

$$\partial_t \mathbf{v}(\mathbf{x}, t) = f(\mathbf{v}(\mathbf{x}, t)) + P(f(\mathbf{v}(\mathbf{x}, t))) = (1 + P)f(\mathbf{v}(\mathbf{x}, t)) \quad (2.10a)$$

$$\partial_t \xi_\lambda(t) = \mathbf{v}(\xi_\lambda, t) \quad (2.10b)$$

2.2.3 Lagrangian form of Navier-Stokes equations

We will in this section rewrite 2.4b in another form. We begin to define a new position system (which is similar to the particle position used in previous section) $\xi_\lambda(t)$:

$$\partial_t \xi_\lambda(t) = \mathbf{v}(\xi_\lambda(t), t) \quad (2.11a)$$

$$\xi_\lambda(t_0) = \xi_\lambda^0 \quad (2.11b)$$

λ is a system of representative that is initialized by initial condition. For a given λ , $\xi_\lambda(t)$ follows the speed at the given point. This position system is called particle coordinate or Lagrangian. $\xi_\lambda(t)$ is called the characteristic.

We then can define the Lagrangian speed.

$$\mathbf{u}_\lambda(t) = \mathbf{v}(\xi_\lambda(t), t) \quad (2.12)$$

The Lagrangian speed is the speed following a characteristic.

Taking the total derivative (the derivative of everything that depend on time) of the Lagrangian speed with respect of time, we have:

$$\frac{d\mathbf{u}_\lambda(t)}{dt} = \frac{d\mathbf{v}(\xi_\lambda(t), t)}{dt} = \partial_t \mathbf{v} + \left(\frac{\partial \xi_\lambda(t)}{\partial t} \cdot \nabla \right) \mathbf{v} \quad (2.13)$$

This can be rewritten:

$$\frac{d\mathbf{u}_\lambda(t)}{dt} = \partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} \quad (2.14)$$

This is exactly the lhs of equation 2.4b.

We then can rewrite Navier-Stokes equations as:

$$\nabla \cdot \mathbf{u}_\lambda(t) = 0 \quad (2.15a)$$

$$\frac{d\mathbf{u}_\lambda(t)}{dt} = -\nabla p(\xi_\lambda(t), t) + \frac{\mathbf{F}(\xi_\lambda(t), t)}{\rho(\mathbf{x}, t)} + \nu \Delta \mathbf{u}_\lambda(t) \quad (2.15b)$$

Remark 2.2.1. *We remark that with this notation some expression like spatial derivative of \mathbf{u} is not defined. In an analytical procedure, we can transform \mathbf{u} to \mathbf{v} with the help of the expression of ξ , then the derivative is well defined. But in a numerical procedure, the point where the values are known are particles. This demand to define derivative on unstructured grid or to interpolate at grid point.*

2.3 Boundary conditions

We will be interested in two kinds of boundary conditions.

Inflow Boundary: An inflow boundary is a source of water.

free surface Boundary: A free surface boundary is a freely moving boundary where the other fluid is inert.

2.3.1 Inflow

Inflow boundary conditions have a constant prescribed speed. This give the following constraint on pressure:

$$\nabla p(\mathbf{x}, t) = f(\mathbf{v}(\mathbf{x}, t)) \quad (2.16)$$

The following alternative boundary conditions have been used. Set the speed on the surface artificially to constant and use 0 Neumann boundary conditions.

2.3.2 Free surface

To define the free surface boundary conditions, we need to define the stress tensor:

$$\sigma_{ij} = -p\delta_{ij} + \nu \left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) \quad (2.17)$$

The boundary conditions are then given by (for 3d):

$$\sum_{i,j} \sigma_{ij} n_i n_j = 0 \quad (2.18)$$

$$\sum_{i,j} \sigma_{ij} t_i^1 n_j = 0 \quad (2.19)$$

$$\sum_{i,j} \sigma_{ij} t_i^2 n_j = 0 \quad (2.20)$$

$$(2.21)$$

Where \mathbf{n} is the normal vector and \mathbf{t}^1 and \mathbf{t}^2 are two non-collinear tangent vectors. For 2d only one tangent vector is needed.

The first equation can be used to find boundary conditions for p . The other equations only depend of speed, because \mathbf{n} is orthogonal to \mathbf{t}^1 and \mathbf{t}^2 . The value of ν is not relevant for the condition (a global non zero constant). The constraint is linear.

3.1 Introduction

We will in this chapter be interested in the case of fixed domain Navier-Stokes with grid discretization. This case is easier than the variable domain case and serve as basis to more complicated case.

We will treat the discretization of time and space separately. We will first begin by time discretization. The space discretization will only be used to evaluate derivatives.

We will in this chapter present two way to solves Navier-Stokes equations. We will show that this two methods are equivalent if a Runge-Kutta method is used to solve. And that we are exactly divergence free.

In next subsection we will present an overview of the two methods.

3.1.1 Analytical expression for pressure

We use the work of section 2.2.1 that Navier-Stokes equations are analytically equivalent to:

$$\partial_t \mathbf{v}(\mathbf{x}, t) = (1 + P)f(\mathbf{v}(\mathbf{x}, t)) \quad (3.1)$$

$1 + P$ projects a non divergence free vector to a divergence free vector. The solution \mathbf{v} is a divergence free vector as long that initial conditions are divergence free. Because the integral of a divergence free vector is again a divergence free vector.

But a priori the numerical solution is not necessary divergence free.

3.1.2 Projection of speed

We can project every speed in a divergence free space:

$$\partial_t \tilde{\mathbf{v}}(\mathbf{x}, t) = f(\mathbf{v}(\mathbf{x}, t)) \quad (3.2a)$$

$$\mathbf{v}(\mathbf{x}, t) = (1 + P)\tilde{\mathbf{v}} \quad (3.2b)$$

We have the certitude to be always divergence free by construction.

3.2 Time discretization and integration

3.2.1 Runge-Kutta method

A Runge-Kutta method is a method to solve the ODE (We drop the \mathbf{x} dependence, but it's understood that this equation is for a vector formed in concatenating every speed):

$$\partial_t \mathbf{v}(t) = f(\mathbf{v}) \quad (3.3)$$

The solution at time $n + 1$ is given from the solution at time n with Δt the time step and a, b parameters of the method.

$$\mathbf{v}_{n+1} = \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \quad (3.4a)$$

$$\mathbf{k}_j = \Delta t f(\mathbf{v}_n + \sum_{i=1}^{j-1} a_{j,i} \mathbf{k}_i) \quad (3.4b)$$

3.2.2 Runge-Kutta based linear projection

We now integrate equations given by methods 3.1.1 and 3.1.2 with a Runge-Kutta method.

The numerical scheme for exact divergence free speed is:

$$\tilde{\mathbf{v}}_{n+1} = \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i + P \left(\tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i \right) \quad (3.5a)$$

$$\tilde{\mathbf{k}}_i = \Delta t f \left(\tilde{\mathbf{v}}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j + P \left(\tilde{\mathbf{v}}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j \right) \right) \quad (3.5b)$$

We project at every estimation of speed. Making by construction every speed divergence free.

Scheme for analytical expression for pressure:

$$\mathbf{v}_{n+1} = \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \quad (3.6a)$$

$$k_i = \Delta t f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \mathbf{k}_j \right) + \Delta t P \left(f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \mathbf{k}_j \right) \right) \quad (3.6b)$$

The following theorem shows that the two schemes are the same.

Theorem 3.1. *If $\mathbf{v}_n = \tilde{\mathbf{v}}_n$ and \mathbf{v}_n is divergence free then $\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$*

Proof We begin to prove the following lemma.

Lemma 3.2.

$$\mathbf{k}_i = \tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i) \quad (3.7)$$

Proof By recurrence on i . We begin with $i = 1$:

$$\mathbf{k}_1 = \Delta t f(\mathbf{v}_n) + \Delta t P(f(\mathbf{v}_n)) \quad (3.8)$$

$$\tilde{\mathbf{k}}_1 = \Delta t f(\mathbf{v}_n) \quad (3.9)$$

$$\mathbf{k}_1 = \Delta t f(\mathbf{v}_n) + \Delta t P(f(\mathbf{v}_n)) = \tilde{\mathbf{k}}_1 + P(\tilde{\mathbf{k}}_1) \quad (3.10)$$

Assuming true for smaller i :

$$\mathbf{k}_i = \Delta t f \left(\mathbf{v}_n + \sum_{j=1}^n a_{ij} k_j \right) + \Delta t P \left(f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \mathbf{k}_j \right) \right)$$

Using the recurrence relation we have:

$$\begin{aligned} &= \Delta t f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \left(\tilde{\mathbf{k}}_j + P(\tilde{\mathbf{k}}_j) \right) \right) + \Delta t P \left(f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \left(\tilde{\mathbf{k}}_j + P(\tilde{\mathbf{k}}_j) \right) \right) \right) \\ \tilde{\mathbf{k}}_i &= \Delta t f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j + P \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j \right) \right) \end{aligned}$$

Using the linearity of P and that $P\mathbf{v}_n = 0$:

$$\begin{aligned} &= \Delta t f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \left(\tilde{\mathbf{k}}_j + P(\tilde{\mathbf{k}}_j) \right) \right) \\ \mathbf{k}_i &= \tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i) \end{aligned}$$

■

We now write the expression for \mathbf{v}_{n+1} and $\tilde{\mathbf{v}}_{n+1}$ using the lemma:

$$\begin{aligned}\mathbf{v}_{n+1} &= \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \\ &= \mathbf{v}_n + \sum_{i=1}^s b_i (\tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i)) \\ \tilde{\mathbf{v}}_{n+1} &= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i + P\left(\tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i\right)\end{aligned}$$

Using the linearity of P and that $P\tilde{\mathbf{v}}_n = 0$

$$= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i (\tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i))$$

Using that $\mathbf{v}_n = \tilde{\mathbf{v}}_n$

$$\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$$

■

Theorem 3.3. *For the implicit Runge-Kutta case, where the sum to $i - 1$ goes now to s . If $\mathbf{v}_n = \tilde{\mathbf{v}}_n$ and \mathbf{v}_n is divergence free then $\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$*

Proof We begin to prove the following lemma.

Lemma 3.4. *After relabeling noting \mathbf{k}_i^j the j -th solution of \mathbf{k}_i . We have for every j .*

$$\mathbf{k}_i^j = \tilde{\mathbf{k}}_i^j + P(\tilde{\mathbf{k}}_i^j) \quad (3.11)$$

This doesn't say that we have existence and unicity of the solution only that if we have a set of solution for \mathbf{k} we have a bijection to solutions of $\tilde{\mathbf{k}}$

Proof Because the sum goes to s and not $i - 1$ we cannot use recurrence. We now will use vector notation for k .

We construct k and \tilde{k} vector with the vector \mathbf{k}_i and $\tilde{\mathbf{k}}_i$

$$k = \begin{pmatrix} \mathbf{k}_1 \\ \vdots \\ \mathbf{k}_s \end{pmatrix} \quad (3.12)$$

$$\tilde{k} = \begin{pmatrix} \tilde{\mathbf{k}}_1 \\ \vdots \\ \tilde{\mathbf{k}}_s \end{pmatrix} \quad (3.13)$$

We form \hat{P} and \hat{f} from a Kronecker product:

$$\hat{P} = 1_s \bigotimes P = \begin{pmatrix} P & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & P \end{pmatrix} \quad (3.14)$$

$$\hat{f} = 1_s \bigotimes f = \begin{pmatrix} f & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & f \end{pmatrix} \quad (3.15)$$

Where for \hat{f} we have used a notation where:

$$\hat{f}(k) = \begin{pmatrix} f(\mathbf{k}_1) \\ \vdots \\ f(\mathbf{k}_n) \end{pmatrix} \quad (3.16)$$

We now define \hat{v}_n :

$$\hat{v}_n = \begin{pmatrix} \mathbf{v}_n \\ \vdots \\ \mathbf{v}_n \end{pmatrix} \quad (3.17)$$

We now define \hat{A} with the following Kronecker product:

$$\hat{A} = \begin{pmatrix} a_{11} & \cdots & a_{1s} \\ \vdots & \ddots & \vdots \\ a_{s1} & \cdots & a_{ss} \end{pmatrix} \bigotimes 1 = A \bigotimes 1 \quad (3.18)$$

\hat{A} and \hat{P} are commutative, because of the mixed-product property.

$$\hat{A}\hat{P} = (A \bigotimes 1) (1_s \bigotimes P) = A \bigotimes P \quad (3.19)$$

$$\hat{P}\hat{A} = (1_s \bigotimes P) (A \bigotimes 1) = A \bigotimes P \quad (3.20)$$

The two expressions can now be written:

$$k = (1 + \hat{P})\Delta t \hat{f}(\hat{v}_n + \hat{A}k) \quad (3.21)$$

$$\tilde{k} = \Delta t \hat{f}((1 + \hat{P})(\hat{v}_n + \hat{A}k)) \quad (3.22)$$

We begin to define 2 functions:

$$k = g(k) \quad (3.23)$$

$$\tilde{k} = \tilde{g}(\tilde{k}) \quad (3.24)$$

$$g(x) = (1 + \hat{P})\Delta t \hat{f}(\hat{v}_n + \hat{A}x) \quad (3.25)$$

$$\tilde{g}(x) = \Delta t \hat{f}((1 + \hat{P})(\hat{v}_n + \hat{A}x)) \quad (3.26)$$

k and \tilde{k} are fixed points of functions g and \tilde{g} .

We now calculate:

$$(1 + \hat{P})\tilde{g}(x) = (1 + \hat{P})\Delta t \hat{f}((1 + \hat{P})(\hat{v}_n + \hat{A}x)) \quad (3.27)$$

Using:

$$\hat{P}\hat{v}_n = 0 \quad (3.28)$$

Using that \hat{A} and \hat{P} commute

$$(1 + \hat{P})\tilde{g}(x) = (1 + \hat{P})\Delta t \hat{f}(\hat{v}_n + \hat{A}(1 + \hat{P})x) \quad (3.29)$$

$$= g((1 + \hat{P})x) \quad (3.30)$$

We now substitute x with \tilde{k}

$$(1 + \hat{P})\tilde{g}(\tilde{k}) = g((1 + \hat{P})\tilde{k}) \quad (3.31)$$

by definition \tilde{k} is a fixed point of \tilde{g}

$$(1 + \hat{P})\tilde{k} = g((1 + \hat{P})\tilde{k}) \quad (3.32)$$

$(1 + \hat{P})\tilde{k}$ is a fixed point of g . But fixed point of g is k .

With relabeling of solution if needed, this directly gives the result with \mathbf{k}^j the j -th solution:

$$\mathbf{k}^j = (1 + \hat{P})\tilde{\mathbf{k}}^j \quad (3.33)$$

This is exactly the vector version of what we wanted to prove. ■

The rest is exactly the same than in the first case. To not overload the proof with notation, we drop the j label to indicate which solution we take.

We now write the expression for \mathbf{v}_{n+1} and $\tilde{\mathbf{v}}_{n+1}$ using the lemma.

$$\begin{aligned} \mathbf{v}_{n+1} &= \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \\ &= \mathbf{v}_n + \sum_{i=1}^s b_i (\tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i)) \\ \tilde{\mathbf{v}}_{n+1} &= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i + P \left(\tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i \right) \\ &= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i (\tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i)) \end{aligned}$$

Using that $\mathbf{v}_n = \tilde{\mathbf{v}}_n$

$$\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$$

■

Corollary 3.5. *Solving Navier-Stokes equation with the analytical good choice of pressure is exactly divergence free at every approximation of speed.*

Proof The expression of \mathbf{v} is the solution of the Navier-Stokes equation with the good choice of pressure. $\tilde{\mathbf{v}}$ is the solution of Runge-Kutta equation without pressure which is projected at every speed estimation. \mathbf{v} and $\tilde{\mathbf{v}}$ are the same by the theorem. ■

Corollary 3.6. *Using the expression for \mathbf{v} or $\tilde{\mathbf{v}}$ we are k order precise in time. Where k is the order of the Runge-Kutta method.*

Proof \mathbf{v} and $\tilde{\mathbf{v}}$ are the same. \mathbf{v} consists only of a Runge-Kutta method with a good chosen function. So the order in time of \mathbf{v} and $\tilde{\mathbf{v}}$ is the same that the method order. ■

3.2.3 Runge-Kutta based affine projection

We will repeat the work in section 3.2.2 but where the projection is an affine operator. We use the notation of 1.4.1.

Scheme for projection at every evaluation of speed:

$$\tilde{\mathbf{v}}_{n+1} = \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i + P \left(\tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i, \tilde{\mathbf{T}}_0 \right) \quad (3.34a)$$

$$\tilde{\mathbf{k}}_i = \Delta t f \left(\tilde{\mathbf{v}}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j + P \left(\tilde{\mathbf{v}}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j, \tilde{\mathbf{T}}_i \right) \right) \quad (3.34b)$$

We project at every estimation of speed. Making by construction every speed divergence free.

Scheme for analytical expression for pressure:

$$\mathbf{v}_{n+1} = \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \quad (3.35a)$$

$$\mathbf{k}_i = \Delta t f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \mathbf{k}_j \right) + \Delta t P \left(f \left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \mathbf{k}_j \right), \mathbf{T}_i \right) \quad (3.35b)$$

The following theorem shows that the two schemes are the same and give the relation between T and \tilde{T} .

Theorem 3.7. *If $\mathbf{v}_n = \tilde{\mathbf{v}}_n$ and \mathbf{v}_n are divergence free then $\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$. With the relation for the translation:*

For $0 < i \leq s$

$$\tilde{\mathbf{T}}_i = \sum_{j=1}^{i-1} a_{ij} \Delta t \mathbf{T}_j \quad (3.36)$$

$$\tilde{\mathbf{T}}_0 = \sum_{i=1}^s b_i \Delta t \mathbf{T}_i \quad (3.37)$$

Proof We begin to prove the following lemma.

Lemma 3.8.

$$\mathbf{k}_i = \tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i, \Delta t \mathbf{T}_i) \quad (3.38)$$

Proof By recurrence on i . We begin with $i = 1$:

$$\mathbf{k}_1 = \Delta t f(\mathbf{v}_n) + \Delta t P(f(\mathbf{v}_n), \mathbf{T}_1) \quad (3.39)$$

$$\tilde{\mathbf{k}}_1 = \Delta t f(\mathbf{v}_n) \quad (3.40)$$

$$\mathbf{k}_1 = \Delta t f(\mathbf{v}_n) + \Delta t P(f(\mathbf{v}_n), \mathbf{T}_1) = \tilde{\mathbf{k}}_1 + P(\tilde{\mathbf{k}}_1, \Delta t \mathbf{T}_1) \quad (3.41)$$

Assuming true for smaller i :

$$\begin{aligned} \mathbf{k}_i &= \Delta t f\left(\mathbf{v}_n + \sum_{j=1}^n a_{ij} \mathbf{k}_j\right) + \Delta t P\left(f\left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \mathbf{k}_j\right), \mathbf{T}_i\right) \\ &= \Delta t f\left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \left(\tilde{\mathbf{k}}_j + P(\tilde{\mathbf{k}}_j, \Delta t \mathbf{T}_j)\right)\right) + \Delta t P\left(f\left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \left(\tilde{\mathbf{k}}_j + P(\tilde{\mathbf{k}}_j, \Delta t \mathbf{T}_j)\right)\right), \mathbf{T}_i\right) \\ \tilde{\mathbf{k}}_i &= \Delta t f\left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j + P\left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \tilde{\mathbf{k}}_j, \tilde{\mathbf{T}}_i\right)\right) \end{aligned}$$

Using the linearity of P and $P\mathbf{v}_n = 0$ and defining $\hat{\mathbf{T}}_j^i$

$$\begin{aligned} &= \Delta t f\left(\mathbf{v}_n + \sum_{j=1}^{i-1} a_{ij} \left(\tilde{\mathbf{k}}_j + P(\tilde{\mathbf{k}}_j, \hat{\mathbf{T}}_j^i)\right)\right) \\ \tilde{\mathbf{T}}_i &= \sum_j^{i-1} a_{ij} \hat{\mathbf{T}}_j^i \\ \hat{\mathbf{T}}_j^i &= \Delta t \mathbf{T}_j \\ \mathbf{k}_i &= \tilde{\mathbf{k}}_i + P(\tilde{\mathbf{k}}_i, \Delta t \mathbf{T}_i) \end{aligned}$$

This prove the relation and give the relation between the two.

$$\tilde{\mathbf{T}}_i = \sum_j^{i-1} a_{ij} \Delta t \mathbf{T}_j \quad (3.42)$$

■

We now write the expression for \mathbf{v}_{n+1} and $\tilde{\mathbf{v}}_{n+1}$ using the lemma.

$$\begin{aligned}
\mathbf{v}_{n+1} &= \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \\
&= \mathbf{v}_n + \sum_{i=1}^s b_i \left(\tilde{\mathbf{k}}_i + P \left(\tilde{\mathbf{k}}_i, \Delta t \mathbf{T}_i \right) \right) \\
\tilde{\mathbf{v}}_{n+1} &= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i + P \left(\tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i, \tilde{\mathbf{T}}_0 \right) \\
&= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \left(\tilde{\mathbf{k}}_i + P \left(\tilde{\mathbf{k}}_i, \hat{\mathbf{T}}_i^0 \right) \right) \\
\tilde{\mathbf{T}}_0 &= \sum_{i=1}^s b_i \hat{\mathbf{T}}_i^0 \\
\tilde{\mathbf{T}}_0 &= \sum_{i=1}^s b_i \Delta t \mathbf{T}_i
\end{aligned}$$

Using that $\mathbf{v}_n = \tilde{\mathbf{v}}_n$

$$\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$$

■

Theorem 3.9. *For the implicit Runge-Kutta case, where the sum on $i - 1$ goes now to s . If $\mathbf{v}_n = \tilde{\mathbf{v}}_n$ and \mathbf{v}_n are divergence free then $\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$. And the translation is given by:*

$$\tilde{\mathbf{T}}_i = \Delta t \sum_j a_{ij} \mathbf{T}_j \quad (3.43)$$

$$\tilde{\mathbf{T}}_0 = \Delta t \sum_j b_j \mathbf{T}_j \quad (3.44)$$

Proof We begin to prove the following lemma.

Lemma 3.10. *After relabeling j noting \mathbf{k}_i^j the j solution of \mathbf{k}_i . We have for every j .*

$$\mathbf{k}_i^j = \tilde{\mathbf{k}}_i^j + P(\tilde{\mathbf{k}}_i^j, \Delta t \mathbf{T}_i) \quad (3.45)$$

This doesn't say that we have existence and unicity of the solution only that if we have a set of solution for k we have a bijection to solution of \tilde{k}

Proof Because the sum goes to s and not $i - 1$ we cannot use recurrence. We now will use vector notation for k .

We construct k and \tilde{k} vectors with the vector \mathbf{k}_i and $\tilde{\mathbf{k}}_i$

$$k = \begin{pmatrix} \mathbf{k}_1 \\ \vdots \\ \mathbf{k}_s \end{pmatrix} \quad (3.46)$$

$$\tilde{k} = \begin{pmatrix} \tilde{\mathbf{k}}_1 \\ \vdots \\ \tilde{\mathbf{k}}_s \end{pmatrix} \quad (3.47)$$

We form \hat{L} the linear part of the projection from L the linear part from the projection P .

$$\hat{L} = 1_s \otimes L = \begin{pmatrix} L & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & L \end{pmatrix} \quad (3.48)$$

We have the following property:

$$\hat{L}\hat{v}_n = 0 \quad (3.49)$$

This is true because \hat{v}_n is divergence free. \hat{L} is the linear part and consist to make the projection with 0 boundary conditions.

τ_i the translation vector from \mathbf{T}_i the translation part of P . τ is the sum of all individual translation.

$$\tau_i = \begin{pmatrix} \mathbf{0} \\ \vdots \\ \mathbf{T}_i \\ \vdots \\ \mathbf{0} \end{pmatrix} \quad (3.50)$$

$$\tau = \sum_i \tau_i = \begin{pmatrix} \mathbf{T}_1 \\ \vdots \\ \mathbf{T}_s \end{pmatrix} \quad (3.51)$$

Same for $\tilde{\tau}_i$ with \mathbf{T}_i changed with $\tilde{\mathbf{T}}_i$

We now form the function \hat{f} from f with:

$$\hat{f} = 1_s \otimes f = \begin{pmatrix} f & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & f \end{pmatrix} \quad (3.52)$$

We now define \hat{v}_n :

$$\hat{v}_n = \begin{pmatrix} \mathbf{v}_n \\ \vdots \\ \mathbf{v}_n \end{pmatrix} \quad (3.53)$$

We now define \hat{A} with the following Kronecker product:

$$\hat{A} = \begin{pmatrix} a_{11} & \dots & a_{1s} \\ \vdots & \ddots & \vdots \\ a_{s1} & \dots & a_{ss} \end{pmatrix} \otimes 1 = A \otimes 1 \quad (3.54)$$

\hat{A} and \hat{L} are commutative, because of the mixed-product property.

$$\hat{A}\hat{L} = (A \otimes 1) (1_s \otimes L) = A \otimes L \quad (3.55)$$

$$\hat{L}\hat{A} = (1_s \otimes L) (A \otimes 1) = A \otimes L \quad (3.56)$$

$$k = (1 + \hat{L})\Delta t \hat{f}(\hat{v}_n + \hat{A}k) + \Delta t\tau \quad (3.57)$$

$$\tilde{k} = \Delta t \hat{f}((1 + \hat{L})(\hat{v}_n + \hat{A}k) + \tilde{\tau}) \quad (3.58)$$

We begin to define 2 functions:

$$k = g(k) \quad (3.59)$$

$$\tilde{k} = \tilde{g}(\tilde{k}) \quad (3.60)$$

$$g(x) = (1 + \hat{L})\Delta t \hat{f}(\hat{v}_n + \hat{A}x) + \Delta t\tau \quad (3.61)$$

$$\tilde{g}(x) = \Delta t \hat{f}((1 + \hat{L})(\hat{v}_n + \hat{A}x) + \tilde{\tau}) \quad (3.62)$$

k and \tilde{k} are fixed points of function g and \tilde{g} .

We now calculate using that L is linear and $L\hat{v} = 0$:

$$(1 + \hat{L})\tilde{g}(x) = (1 + \hat{L})\Delta t \hat{f}((1 + \hat{L})(\hat{v}_n + \hat{A}x) + \tilde{\tau}) = (1 + \hat{L})\Delta t \hat{f}(\hat{v}_n + \hat{A}(1 + \hat{L})x + \tilde{\tau}) \quad (3.63)$$

$$= (1 + \hat{L})\Delta t \hat{f}(\hat{v}_n + \hat{A}((1 + \hat{L})x + \hat{A}^{-1}\tilde{\tau})) \quad (3.64)$$

By definition of g we have:

$$= g((1 + \hat{L})x + \hat{A}^{-1}\tilde{\tau}) - \Delta t\tau \quad (3.65)$$

We now substitute \tilde{k} in x

$$(1 + \hat{L})\tilde{g}(\tilde{k}) = g((1 + \hat{L})\tilde{k} + \hat{A}^{-1}\tilde{\tau}) - \Delta t\tau \quad (3.66)$$

\tilde{k} is a fixed point of \tilde{g}

$$(1 + \hat{L})\tilde{k} = g((1 + \hat{L})\tilde{k} + \hat{A}^{-1}\tilde{\tau}) - \Delta t\tau \quad (3.67)$$

$$(1 + \hat{L})\tilde{k} + \Delta t\tau = g((1 + \hat{L})\tilde{k} + \hat{A}^{-1}\tilde{\tau}) \quad (3.68)$$

If

$$\tilde{\tau} = \Delta t \hat{A}\tau \quad (3.69)$$

Then

$$(1 + \hat{L})\tilde{k} + \Delta t\tau = g((1 + \hat{L})\tilde{k} + \Delta t\tau) \quad (3.70)$$

$(1 + \hat{L})\tilde{k} + \Delta t\tau$ is a fixed point of g . But fixed point of g is k .

After relabeling of solution, this directly gives the result with k^j the j -th solution:

$$k^j = (1 + \hat{L})\tilde{k}^j + \Delta t\tau \quad (3.71)$$

This is exactly the vector version of what we wanted to prove. ■

The rest is exactly the same than in the first case. To not overload the proof with notation, we drop the j label to indicate which solution we take.

We now write the expression for \mathbf{v}_{n+1} and $\tilde{\mathbf{v}}_{n+1}$ using the lemma.

$$\begin{aligned}\mathbf{v}_{n+1} &= \mathbf{v}_n + \sum_{i=1}^s b_i \mathbf{k}_i \\ &= \mathbf{v}_n + \sum_{i=1}^s b_i \left((1 + L) \tilde{\mathbf{k}}_i + \Delta t \mathbf{T}_i \right) \\ \tilde{\mathbf{v}}_{n+1} &= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i + L \left(\tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i \tilde{\mathbf{k}}_i \right) + \tilde{\mathbf{T}}_0 \\ &= \tilde{\mathbf{v}}_n + \sum_{i=1}^s b_i (1 + L) \tilde{\mathbf{k}}_i + \tilde{\mathbf{T}}_0 \\ \tilde{\mathbf{T}}_0 &= \Delta t \sum_{i=1}^s b_i \mathbf{T}_i\end{aligned}$$

Using that $\mathbf{v}_n = \tilde{\mathbf{v}}_n$

$$\mathbf{v}_{n+1} = \tilde{\mathbf{v}}_{n+1}$$
■

3.3 Spatial discretization

3.3.1 Non-staggered grid

On a non-staggered grid we put the variable like figure 3.1. The problem with non-staggered grid, is that obvious center difference discretization lead to wrong divergence free vector.

We define the derivative of a scalar by:

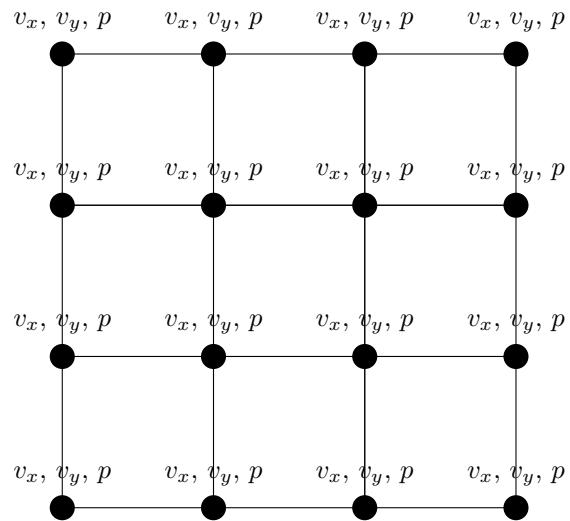

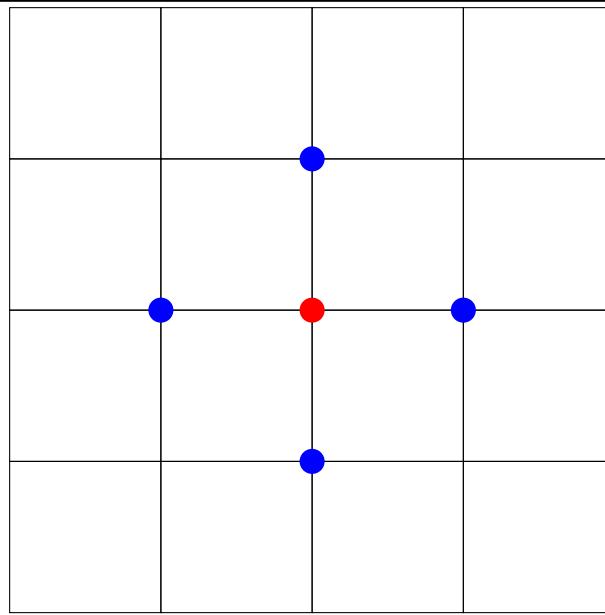

$$\partial_x a_i = \frac{a_{i+1} - a_i - 1}{\Delta x} \tag{3.72}$$

The divergence discretization is then given by (notation for 2d, but for 3d it's the same):

$$\nabla \cdot \mathbf{v}_{i,j} = \frac{v_{x i+1,j} - v_{x i-1,j}}{\Delta x} + \frac{v_{y i+1,j} - v_{y i-1,j}}{\Delta y} \tag{3.73}$$

The problem can be seen in figure 3.2 is that the divergence at red point only use value at blue point and not the point at center (red point). This allows to have non-physical solutions that are divergence free.

In figure 3.3 we have a solution that is numerically divergence free. But this solution is not continuous and we expect that is not divergence free.

**Figure 3.1:** Position of variable for Non-Staggered grid**Figure 3.2:** Values used to calculate the divergence at red point are in blue

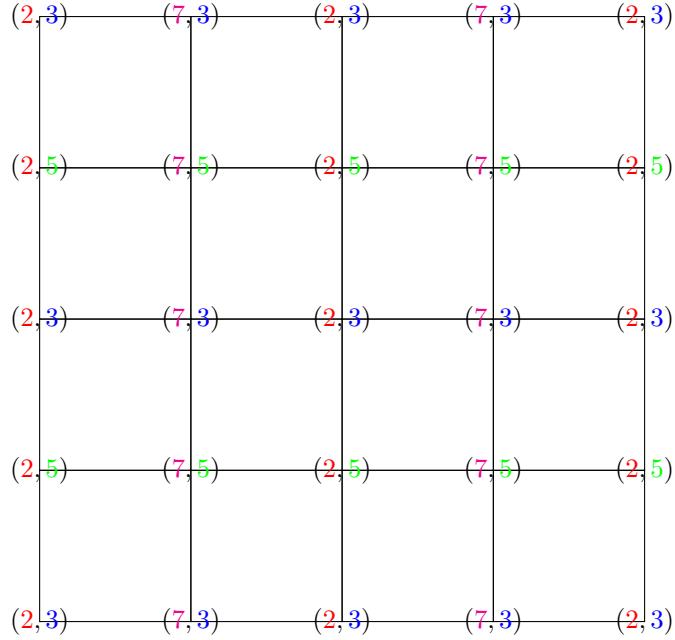

Figure 3.3: Speed that are numerically divergence free but shouldn't

The problem with this kind of solution, is that it's very stable. The projection operator P will be 0, and doesn't correct this kind of speed. We cannot correct it in general for every choice of f . Note that all the work done in section 3.2 is true. In particular the theorem will be true and will correctly projects in a divergence free space. It's only that our divergence free space contains solutions that are not wanted.

We can recall one of the formulations of the so called Murphy's law, "If anything can go wrong, it will."

We can correct this problem with using a forward or backward expression. But this kind of expression is only first order accurate. Another solution is to use another grid.

3.3.2 Staggered grid

On a staggered grid we put the variable in the position shown if figure 3.4.

This can seem to be strange to have different component of speed at different places. But it make discretization more easy. To label variable, we label by cell and then took the lower left component (cf. figure 3.5).

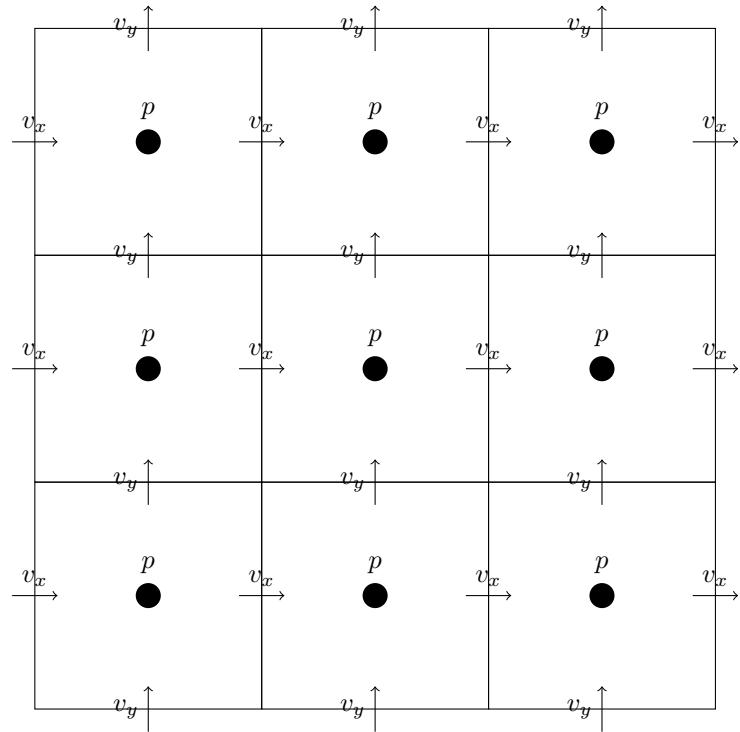

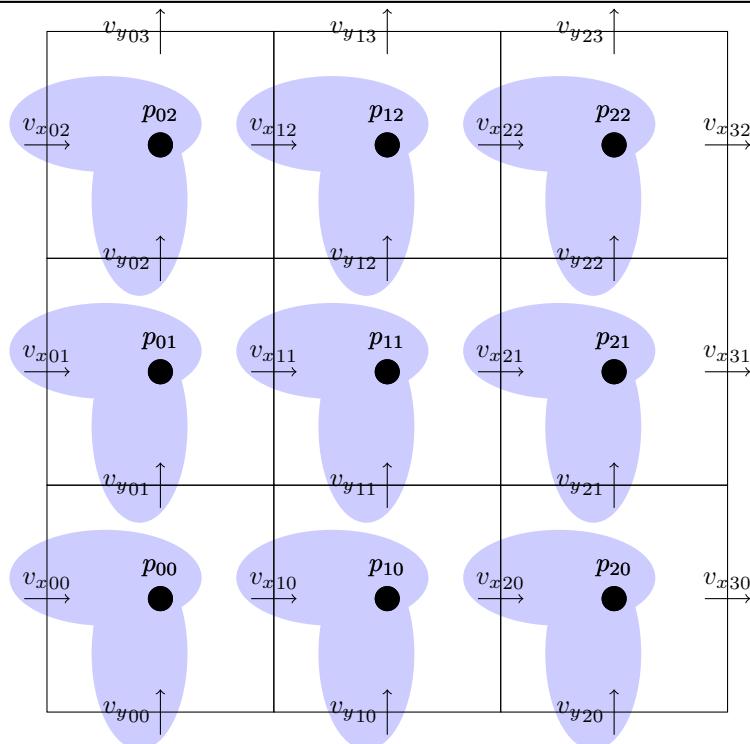

We now define the divergence and the gradient:

$$\nabla p_{ij} = \begin{pmatrix} \frac{p_{i,j} - p_{i-1,j}}{\Delta x} \\ \frac{p_{i,j} - p_{i,j-1}}{\Delta y} \end{pmatrix} \quad (3.74)$$

$$\nabla \cdot \mathbf{v}_{i,j} = \frac{v_{x,i+1,j} - v_{x,i,j}}{\Delta x} + \frac{v_{y,i,j+1} - v_{y,i,j}}{\Delta y} \quad (3.75)$$

This two expressions are geometrically very clear.

In figure 3.6, the gradient at red speed component uses components at blue point. Contrary at case with center difference we cannot create a none constant vector with 0 gradient.

**Figure 3.4:** Position of variable on a staggered grid**Figure 3.5:** Labeling on staggered grid

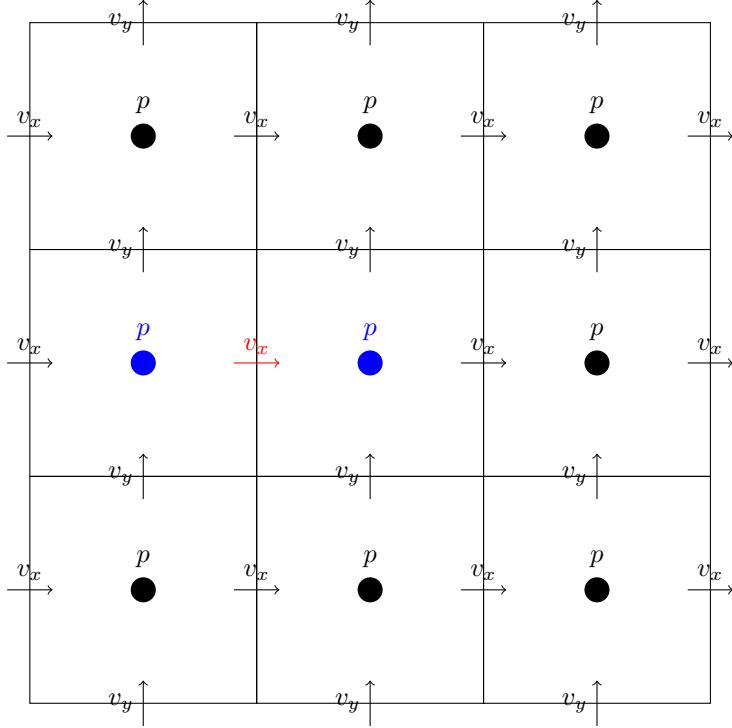

Figure 3.6: Points used to calculate the red gradient component are in blue

The divergence is given by the sum of inflow around a cell. In figure 3.7, the divergence at red point uses components at blue point.

We cannot have the same situation than without staggered grid, where a nonphysical vector is divergence free.

Discretization

We now look at different possible schemes for staggered grid discretization.

Gradient The gradient is discretized with center difference.

$$\nabla p_{i,j} = \begin{pmatrix} \frac{p_{i-1,j} - p_{i,j}}{\Delta x} \\ \frac{p_{i,j-1} - p_{i,j}}{\Delta y} \end{pmatrix} \quad (3.76)$$

Center difference is second order accurate to the contrary of forward or backward difference.

Divergence The divergence is discretized with center difference.

$$\nabla \cdot \mathbf{v}_{i,j} = \frac{v_{xi,j} - v_{xi-1,j}}{\Delta x} + \frac{v_{yi,j} - v_{yi,j-1}}{\Delta y} \quad (3.77)$$

Because of center difference its second order accurate.

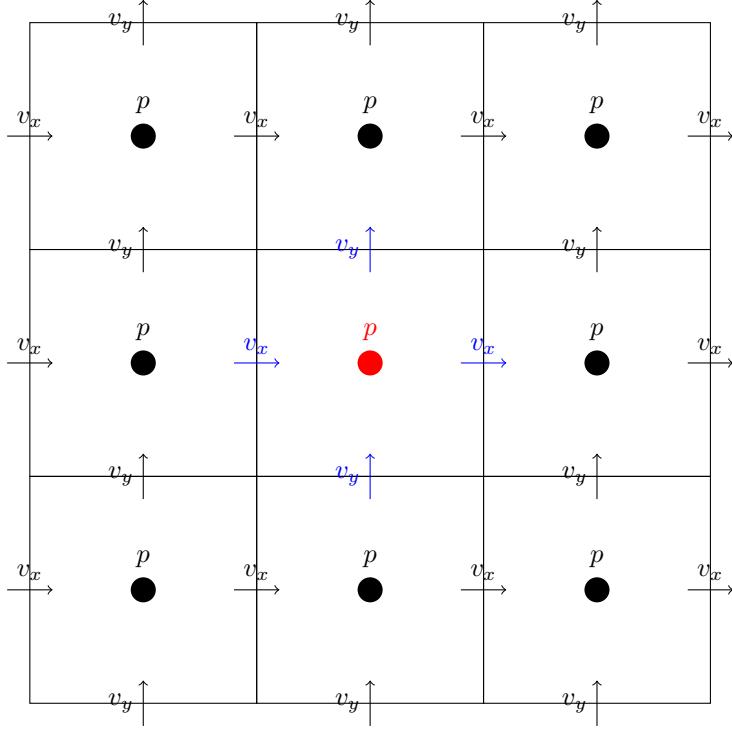

Figure 3.7: Points used to calculate red divergence are in blue

Laplacian The discretization of the Laplacian is the combination of the application of the gradient and divergence.

$$\Delta p_{i,j} = \frac{p_{i+1,j} - 2p_{i,j} + p_{i-1,j}}{(\Delta x)^2} + \frac{p_{i,j+1} - 2p_{i,j} + p_{i,j-1}}{(\Delta y)^2} \quad (3.78)$$

This formula is of order 2. We prove it for the one dimensional case:

$$f(x + \Delta x) - 2f(x) + f(x - \Delta x) =$$

We make a Taylor expansion around x

$$\begin{aligned} &= f(x) + \Delta x f'(x) + (\Delta x)^2 \frac{f''(x)}{2} + (\Delta x)^3 \frac{f'''(x)}{6} + O((\Delta x)^4) - 2f(x) \\ &\quad + f(x) - \Delta x f'(x) + (\Delta x)^2 \frac{f''(x)}{2} - (\Delta x)^3 \frac{f'''(x)}{6} \\ &= (\Delta x)^2 f''(x) + O((\Delta x)^4) \\ f''(x) &= \frac{f(x + \Delta x) - 2f(x) + f(x - \Delta x)}{(\Delta x)^2} + O((\Delta x)^2) \end{aligned}$$

Vector laplacian For vector Laplacian we use the same scheme as in section 3.3.2 but for every component of speed. Staggered grid doesn't pose problem because we don't have mixed terms with derivative and non derivative.

Convection Convection term is the more difficult term to treat, because it's non linear and uses mixed terms. We need to consider two type of terms. Let $i \neq j$ and \mathbf{k} be an

integer vector of the position on the grid and \mathbf{e}_i the i -th unit vector. We first consider as i -th component:

$$(v^i \partial_i v^i)_{\mathbf{k}}^i \quad (3.79)$$

We can discretize this in two manners:

Central difference

$$v^i_{\mathbf{k}} \frac{v^i_{\mathbf{k}+\mathbf{e}_i} - v^i_{\mathbf{k}-\mathbf{e}_i}}{2\Delta x_i} \quad (3.80)$$

Upwind difference We use the same method, but instead to use center difference, we use upwind:

if $v^i_{\mathbf{k}} < 0$

$$(v^i \partial_i v^i)_{\mathbf{k}} = v^i_{\mathbf{k}} \frac{v^i_{\mathbf{k}+\mathbf{e}_i} - v^i_{\mathbf{k}}}{\Delta x_i} \quad (3.81)$$

if $v^i_{\mathbf{k}} > 0$

$$(v^i \partial_i v^i)_{\mathbf{k}} = v^i_{\mathbf{k}} \frac{v^i_{\mathbf{k}} - v^i_{\mathbf{k}-\mathbf{e}_i}}{\Delta x_i} \quad (3.82)$$

if $v^i_{\mathbf{k}} = 0$

$$(v^i \partial_i v^i)_{\mathbf{k}} = 0 \quad (3.83)$$

Upwind is considered more stable (can be proof easily in one dimension for burger's equation) but more diffusive.

We now consider:

$$(v^j \partial_j v^i)_{\mathbf{k}}^i \quad (3.84)$$

Remark 3.3.1. Contrary to the other case, we need to have the speed at a position not known for v^j . This comes because of the staggered grid scheme. For this, we can interpolate the known speed of neighbor cell taking for example the average of the 4 neighbor (cf. figure 3.8). We will use as notation v^{ji} for the speed component j at position for the component i .

We can discretize this in two manners:

Central difference

$$(v^j \partial_j v^i)_{\mathbf{k}}^i = v^{ji}_{\mathbf{k}} \frac{v^i_{\mathbf{k}+\mathbf{e}_j} - v^i_{\mathbf{k}-\mathbf{e}_j}}{2\Delta x_j} \quad (3.85)$$

Upwind difference We use the same method, but instead to use center difference, we use upwind:

if $v^{ji}_{\mathbf{k}} < 0$

$$(v^j \partial_j v^i)_{\mathbf{k}}^i = v^{ji}_{\mathbf{k}} \frac{v^i_{\mathbf{k}+\mathbf{e}_j} - v^i_{\mathbf{k}}}{\Delta x_j} \quad (3.86)$$

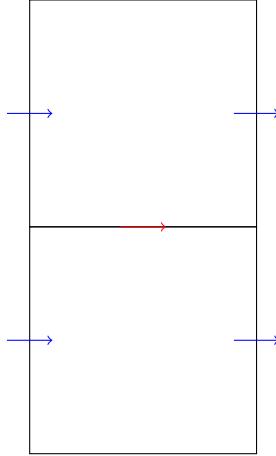

Figure 3.8: We need the value of the red arrow. For this we can interpolate from the blue arrows.

if $v^{ji} \mathbf{k} > 0$

$$(v^j \partial_j v^i)_{\mathbf{k}}^i = v^{ji} \mathbf{k} \frac{v^i \mathbf{k} - v^i \mathbf{k} - e_j}{\Delta x_j} \quad (3.87)$$

if $v^{ji} \mathbf{k} = 0$

$$(v^j \partial_j v^i)_{\mathbf{k}}^i = 0 \quad (3.88)$$

Upwind is considered more stable (can be proven easily in one dimension for burger's equation) but more diffusive.

3.4 Pseudo code

The pseudo code is not very complicate in principle. We need to put all mathematical discretizations and pieces together.

We will use the following order of operation:

1. Calculate optimal time step.
2. Use a Runge-Kutta algorithm. We now have two choices:
 - (a) We project the acceleration. For this we do the following for every Runge-Kutta step:
 - i. We set the speed to the wanted boundary conditions.
 - ii. We calculate the acceleration from discretization of the function noted $f(\mathbf{v})$ in this section.
 - iii. We project the given acceleration.
 - (b) We project the speed. For this we apply the Runge-Kutta step as in section 3.2.2:
 - i. We set the speed to the wanted boundary conditions.
 - ii. We obtain a speed estimation from $f(\mathbf{v})$.

iii. We project the speed estimation to be divergence free.

The principal difference of the two methods are:

- If we project on speed we are always divergence free.
- If we project on force, we need to have initial speeds that are divergence free. Numerical error can accumulate. We can eliminate them with a projection of speed.
- Boundary conditions need to be transformed as in section 3.2.3.

We will in the next section show the implementation of principals parts.

3.4.1 Pseudo code semantic and notation.

The notation of pseudo code is inspired of **C-like** language.

Variables are introduced when used by giving their name.

Affectations are done with \leftarrow which indicate that the left variable take the right value.

Boolean operations are done with there standard mathematical notation ($=, \neq, <, >, \leq, \geq$).

Arithmetic operations uses the standard mathematical operation ($+, -, \cdot, \frac{x}{x}$).

The following special control flow operation are used:

Loop: An infinite loop, is only stopped by a **break** or **return** statement.

For all: A loop which takes all elements of a container. **for all** expressions are normally good candidates for parallelism.

Container

The following container will be used:

Grid: Consists of all cell. Used in expression like **for all**($it \in Grid$).

Unordered Stack: A container where elements can be added and accessed in a **for all**. The order are not important. After usage, the stack is no more used. Duplicate elements are inserted more than one time. A new unordered stack is created with the function call **newunorderedstack()**.

Set: A set is a container which is like a mathematical set, where elements can be added and each element accessed. The difference with a stack is that in a set duplicate elements are stored once and the set element are not discarded after usage. A new set is created with the function call **newset()**.

Data type

The first data type is the *cell*. The *cell* are element of the grid container.

The principal method defined on a cell are:

SpeedGet(*i*) : Which gets the speed at direction *i*. We use staggered grid and consider speed component of a given cell to be below left.

SpeedGet() : Which gets the speed vector.

SpeedSet(*i, val*) : Sets the speed component *i* with value *val*.

SpeedSet(*val*) : Sets the speed vector to value *val*.

AccelerationGet(*i*) : Which gets the acceleration at direction *i*.

AccelerationGet() : Which gets the acceleration vector.

AccelerationSet(*i, val*) : Sets the acceleration component *i* with value *val*.

AccelerationSet(*val*) : Sets the acceleration vector to value *val*.

PressureGet() : Gets the pressure at given cell.

PressureSet(*val*) : Sets the pressure at given cell to *val*.

GetIsFluid() : Indicates if the cell is fluid or not.

GetIsAir() : Indicates if the cell is air or not. This is the opposite of **GetIsFluid()**.

FluidSet() : Sets the cell as fluid.

AirSet() : Sets the cell as air.

GetNeighbour(*dir, s*) : Gets the neighbor cell in direction *dir* positif or negatif depending on the sign of *s*.

We define the following method for vector:

Get(*i*) Gets the value at indice *i* of the vector.

Set(*i, val*) Sets the value at indice *i* of the vector with value *val*.

The following global variables are used:

viscosity : Is the viscosity used.

dt : The time step used.

t : The time.

h : The spacing.

3.4.2 Acceleration evaluation

To apply gravity we simply add a constant acceleration cf. algorithm 2 and algorithm 3. We test if we need to apply gravity with code like algorithm 1 which apply gravity to speed component that touch fluid.

To apply the viscosity we need to calculate the Laplacian and a condition of when apply. The same condition as for gravity work. The application is in algorithm 4 the calculation of the Laplacian is in algorithm 5.

For the convection the application is in algorithm 6 the condition is similar than for Gravity. The convection speed derivative with upwind is done in algorithm 7 and algorithm 8.

Algorithm 1 Algorithm which test if gravity acceleration need to be applied

```

1: function NEEDTOAPPLYGRAVITY(cell)
2:   if cell.GetIsFluid() then
3:     return true  $\triangleright$  We are a fluid cell, so the speed component in y is bordering the fluid cell.
4:   end if
5:   cell2  $\leftarrow$  cell.GetNeighbour(2, -1)  $\triangleright$  We now consider the cell below (the gravity is applied
   in the y direction), to see if we are bordering a fluid cell.
6:   if not(cell2.IsValid()) then
7:     return false  $\triangleright$  If the neighbor doesn't exist we are not near fluid.
8:   end if
9:   if cell2.GetIsFluid() then
10:    return true  $\triangleright$  If the neighbor is fluid, we are bordering a fluid cell.
11:   end if
12:   return false
13: end function
```

Algorithm 2 Algorithm which apply the gravity acceleration.

```

1: function APPLYGRAVITY(cell)
2:   if NeedToApplyGravity(cell) then
3:     cell.AccelerationSet(2, cell.AccelerationGet(2) - g)  $\triangleright$  Add gravity to the acceleration.
4:   end if
5: end function
```

Algorithm 3 Algorithm which apply the gravity acceleration for every cell.

```

1: procedure APPLYGRAVITYCELL
2:   for all cell  $\in$  Grid do
3:     ApplyGravity(cell)
4:   end for
5: end procedure
```

3.4.3 Projection of acceleration.

The projection of acceleration is done in following the following step:

1. Calculate the divergence of the acceleration (*a* is the acceleration).

$$b = \nabla \cdot a \quad (3.89)$$

Algorithm 4 Algorithm which apply the viscosity acceleration.

```

1: procedure APPLYVISCOSITY
2:   for all  $cell \in Grid$  do
3:     if GetIfApplyViscosity( $it$ ) then
4:        $it$ .AccelerationSet( $it$ .AccelerationGet() + GetLaplacianSpeed( $it$ )  $\cdot$  viscosity)  $\triangleright$ 
      Add the viscosity acceleration to the acceleration.
5:     end if
6:   end for
7: end procedure

```

Algorithm 5 Algorithm which applies the vector Laplacian. The discretization is detailed in section 3.3.2

```

1: function GETLAPLACIANSPEED( $cell$ )
2:   for  $i = 1$  to  $dim$  do  $\triangleright$  A vector Laplacian consist to apply the Laplacian to all component.
3:      $temp \leftarrow 0$ 
4:     for  $j = 1$  to  $dim$  do  $\triangleright$  Calculate the Laplacian
5:        $temp \leftarrow temp - 2cell$ .SpeedGet( $i$ )  $\cdot$  ( $h$ .Get( $j$ )) $^2$ 
6:        $temp \leftarrow temp + cell$ .GetNeighbour( $j, 1$ ).SpeedGet( $i$ )  $\cdot$  ( $h$ .Get( $j$ )) $^2$ 
7:        $temp \leftarrow temp + cell$ .GetNeighbour( $j, -1$ ).SpeedGet( $i$ )  $\cdot$  ( $h$ .Get( $j$ )) $^2$ 
8:     end for
9:      $ret$ .Set( $i, temp$ )  $\triangleright$  Store the component in the vector  $ret$ .
10:    end for  $\triangleright$  return the result.
11:   return  $ret$ 
12: end function

```

Algorithm 6 Algorithm to apply the convection.

```

1: function APPLYCONVECTION
2:   for all  $it \in Grid$  do
3:     for  $i = 1$  to  $dim$  do
4:       if GetIfApplyConvection( $it, i$ ) then
5:          $it$ .AccelerationSet( $i, it$ .AccelerationGet( $i$ ) + GetConvectionSpeed( $it, i$ ))  $\triangleright$ 
          We add to the acceleration the convection.
6:       end if
7:     end for
8:   end for
9: end function

```

Algorithm 7 Algorithm which calculates $u_j \partial_j u_i$ with upwind scheme. The discretization is detailed in section 3.3.2

```

1: function GETCONVECTIONELEMENT( $i, j, cell$ )
2:    $U \leftarrow \text{GetSpeedAtBound}(cell, i, j)$             $\triangleright$  Function to get the speed at speed component
   position  $i$  in direction  $j$ . This can be done by average.
3:   if  $U > 0$  then                                 $\triangleright$  We test if we are upwind or not.
4:      $U1 \leftarrow cell.\text{SpeedGet}(i)$ 
5:      $cell \leftarrow cell.\text{GetNeighbour}(j, -1)$ 
6:      $U2 \leftarrow cell.\text{SpeedGet}(i)$ 
7:      $U \leftarrow U(U1 - U2) \cdot h.\text{Get}(j)$ 
8:   else
9:      $U1 \leftarrow cell.\text{SpeedGet}(i)$ 
10:     $cell \leftarrow cell.\text{GetNeighbour}(j, 1)$ 
11:     $U2 \leftarrow cell.\text{SpeedGet}(i)$ 
12:     $U \leftarrow U(U2 - U1) \cdot h.\text{Get}(j)$ 
13:   end if
14:   return  $U$ 
15: end function
```

Algorithm 8 Algorithm which calculates the convection.

```

1: function GETCONVECTIONSPEED( $cell, i$ )
2:    $ret \leftarrow 0$ 
3:   for  $j = 1$  to  $dim$  do                                 $\triangleright$  We sum on  $j$  of  $u_j \partial_j u_i$ .
4:      $ret \leftarrow ret - \text{GetConvectionElement}(i, j, cell)$ 
5:   end for
6:   return  $ret$ 
7: end function
```

2. Solve the linear system

$$\Delta p = b \quad (3.90)$$

3. Change the acceleration to:

$$a_{new} = a - \nabla p \quad (3.91)$$

If we have boundary conditions, the b vector need to be translated. The divergence is calculated by algorithm 9, the gradient by algorithm 10. A function **GetIsInDomain**($cell$) is used, we can consider it similar to $cell.\text{GetIsFluid}()$. The pressure is then solved with algorithm 11.

Algorithm 9 Algorithm that calculates the divergence. The discretization is detailed in section 3.3.2

```

1: function GETDIVERGENCE( $cell$ )
2:    $ret \leftarrow 0$ 
3:   for  $i = 1$  to  $dim$  do
4:      $ret \leftarrow ret - cell.\text{SpeedGet}(i) \cdot h.\text{Get}(i)$ 
5:      $ret \leftarrow ret + cell.\text{GetNeighbour}(i, 1).\text{SpeedGet}(i) \cdot h.\text{Get}(i)$ 
6:   end for
7:   return  $ret$ 
8: end function
```

Algorithm 10 Algorithm that calculates the gradient. The discretization is detailed in section 3.3.2.

```

1: function GETGRADIANT(cell, i)
2:   ret  $\leftarrow$  cell. PressureGet()  $\cdot$  h. Get(i)
3:   ret  $\leftarrow$  ret  $-$  cell. GetNeighbour(i, -1). PressureGet()  $\cdot$  h. Get(i)
4:   return ret
5: end function

```

Algorithm 11 Algorithm to calculate the correction to acceleration to make divergence free. In this case we assume a case with 0 Dirichlet boundary conditions.

```

1: procedure PROJECTACCELERATION
2:   for all it  $\in$  Grid do       $\triangleright$  We calculate the divergence for every cell and store it in a array.
   it. ID() is a unique numbering of the array for all cell.
3:     if it. GetIsInDomain() then
4:       b[it. ID()]  $\leftarrow$  GetDivergence(it)
5:     end if
6:   end for
7:   Grid. SolveLinear(b, p)       $\triangleright$  We solve the Laplacian system. p is the result and b the second
   member. The discretization of Laplacian is shown in section 3.3.2.
8:   for all it  $\in$  Grid do
9:     if it. GetIsInDomain() then  $\triangleright$  If we are in the domain for the Laplacian. We copy the
   result in the pressure.
10:    it. PressureSet(p[it.ID()])
11:   else                                 $\triangleright$  For Dirichlet boundary conditions, we set pressure to 0.
12:     PressureSet(0)
13:   end if
14:   end for
15:   for all it  $\in$  Grid do           $\triangleright$  We correct the acceleration.
16:     for i = 1 to dim do
17:       it. AccelerationSet(i, it. AccelerationGet(i) – GetGradiant(it, i))
18:     end for
19:   end for
20: end procedure

```

3.4.4 Runge-Kutta integration

To implement the Runge-Kutta method, some new elements are needed. We need to have a copy of speed. To do this we add a method **GetArray**(*i*) which gets the array *i*. We need to set the default array if no array is precised this is done by function *SetArraySpeed*(*i*). By default if not changed array 0 is used. The function **CalculateAcceleration()** calculates the acceleration using the default array. The only part of code that uses explicit array is this one.

The function **CalculateAcceleration()** consists to calculate the acceleration and then do the projection. This is shown in algorithm 12.

The Runge-Kutta algorithm for order 4 is shown in algorithm 13. Depending of the Runge-Kutta scheme choosed the number of copy of speed needed change.

Algorithm 12 Algorithm which calculates the acceleration.

```

1: procedure CALCULATEACCELERATION
2:   ApplyConvection()
3:   ApplyViscosity()
4:   ApplyGravityCell()
5:   ProjectAcceleration()
6: end procedure

```

3.4.5 Complexity

The complexity is dominated by the 4 call to **CalculateAcceleration()**. Function **CalculateAcceleration()** then call the function to calculate acceleration. This function consist for cell where the acceleration apply to calculate a term which depend of the cell itself and his neighbor. The complexity is then linear on the number of cell. The complexity for the projection of acceleration will depend on the complexity to solve the Laplacian which depending on the method used can be linear (multigrid for example is linear). The complexity to calculate the gradient is linear too. The complexity is then dominated by the complexity to solve the Laplacian.

A more technical complexity is the storage of data on grid. For fixed topology we can use a fixed size array. But for variable topology we need to choose how we store the data. To be robust, our method need to be able to do dynamic allocation of memory to be able to represent all possible topology. Depending the choice made the average access time can be constant or $\log(n)$ and the worst case can be n . The method **GetNeighbour**(*dir, s*) was used instead of index vector manipulation because it allow to create storage with fast access to neighbor cell.

3.4.6 Parallelism

We remark that we can without problem make parallel the **for all** loop, because we have no dependency:

- The calculation of the acceleration doesn't modify the speed and only reads there proper acceleration.
- The projection of acceleration when applying the gradient uses the already calculated pressure.

Algorithm 13 Algorithm that integrate with the Runge Kutta method.

```

1: procedure RUNGEKUTTA
2:   for all  $it \in Grid$  do
3:      $it.\text{AccelerationSet}(0)$        $\triangleright$  We set the acceleration to 0. So that we can calculate the
   acceleration after.
4:   end for
5:   CalculateAcceleration()  $\triangleright$  This function will add the acceleration to the acceleration array.
6:   for all  $it \in Grid$  do
7:      $it.\text{GetArray}(2).\text{SpeedSet}(it.\text{GetArray}(0).\text{SpeedGet}()$           +
 $it.\text{AccelerationGet}() \cdot dt \cdot 0.5)$   $\triangleright$  Array 2 is set to the speed for the next evaluation. We do
   not use array 0 because we need it.
8:      $it.\text{GetArray}(1).\text{SpeedSet}(it.\text{GetArray}(0).\text{SpeedGet}() + it.\text{AccelerationGet}() \cdot \frac{dt}{6})$ 
    $\triangleright$  Array 1 is set to the accumulation of the result.
9:   end for
10:  for all  $it \in Grid$  do
11:     $it.\text{AccelerationSet}(0)$ 
12:  end for
13:  SetArraySpeed(2)       $\triangleright$  The speed for the next evaluation is in array 2. We set array 2 as
   default.
14:   $t \leftarrow t + 0.5 \cdot dt$ 
15:  CalculateAcceleration()
16:  for all  $it \in Grid$  do
17:     $it.\text{GetArray}(2).\text{SpeedSet}(it.\text{GetArray}(0).\text{SpeedGet}() + it.\text{AccelerationGet}() \cdot \frac{dt}{2})$ 
    $\triangleright$  Array 2 is set to the speed for the next evaluation. We do not use array 0 because we need it.
18:     $it.\text{GetArray}(1).\text{SpeedSet}(it.\text{GetArray}(1).\text{SpeedGet}() + it.\text{AccelerationGet}() \cdot \frac{dt}{3})$ 
    $\triangleright$  Array 1 is set to the accumulation of the result.
19:  end for
20:  for all  $it \in Grid$  do
21:     $it.\text{AccelerationSet}(0)$ 
22:  end for
23:  CalculateAcceleration()
24:  for all  $it \in Grid$  do
25:     $it.\text{GetArray}(2).\text{SpeedSet}(it.\text{GetArray}(0).\text{SpeedGet}() + it.\text{AccelerationGet}() \cdot dt)$ 
26:     $it.\text{GetArray}(1).\text{SpeedSet}(it.\text{GetArray}(1).\text{SpeedGet}() + it.\text{AccelerationGet}() \cdot \frac{dt}{3})$ 
27:  end for
28:  for all  $it \in Grid$  do
29:     $it.\text{AccelerationSet}(0)$ 
30:  end for
31:   $t \leftarrow t + \frac{dt}{2}$ 
32:  CalculateAcceleration()
33:  for all  $it \in Grid$  do
34:     $it.\text{GetArray}(0).\text{SpeedSet}(it.\text{GetArray}(1).\text{SpeedGet}() + it.\text{AccelerationGet}() \cdot \frac{dt}{6})$ 
    $\triangleright$  Array 0 now contain the new speed.
35:  end for
36:  SetArraySpeed(0)  $\triangleright$  We set the default array again to 0 to be ready for the next time step.
37: end procedure

```

- The parallelism to solve the linear system will depend on the method used.

But technically this is only true if the method of manipulation of speed are thread safe.

3.4.7 Conclusion

We have shown a working pseudo code that solve the Navier-Stokes equation for fixed boundary conditions. We have shown that the complexity is dominated by the resolution of a Laplacian and can be linear. To have a real implementation we need to provide some storage related function to access neighbor for example.

This pseudo code is part of the simplified version of the original **C++** code. As linear solver Umfpack direct solver was used. Other iteratif libraries were tested too. The storage methods are constructed around **C++11** standard library **Unordered Map** container which consist of a hash table.

3.5 Numerical experiment

We will now do some numerical experiment in fixed boundary conditions to show how it works.

3.5.1 Heat equation

The more complicated term in the Navier-Stokes equation in grid representation is the convection term, because it's non linear.

$$(\mathbf{v} \cdot \nabla) \mathbf{v} \quad (3.92)$$

We can have this term 0 everywhere, if we ensure that the direction of variation is orthogonal to the direction of speed.

For example, for a two dimensional problem we work with a flow with a speed only in the y direction. And the value depending only on the position on the x axis.

$$\mathbf{v} = \begin{pmatrix} 0 \\ f(x, t) \end{pmatrix} \quad (3.93)$$

The convection term is then:

$$(f(x) \partial_y) \begin{pmatrix} 0 \\ f(x, t) \end{pmatrix} = 0 \quad (3.94)$$

The Navier-Stokes equations reduces then to:

$$\partial_y f(x, t) = 0 \quad (3.95)$$

$$\frac{\partial f(x, t)}{\partial t} = F(x, t) + \nu \frac{\partial^2 f(x, t)}{\partial x^2} - \nabla p \quad (3.96)$$

Equation 3.95 is automatically true because we have no dependence on x . The pressure term role is only to cancel non divergence free part coming from the force. Because the part with the viscosity ν is a linear operator of a divergence free term. For a potential force like gravity, the force can be absorbed in the pressure with a proper

account of boundary conditions. This equation is an equation of heat. We consider no external force as gravity. We will consider as domain $x = [0, 2L]$ with fixed speed in $x = 0$ and $x = L$, Neumann boundary conditions for pressure in $x = 0$ and $x = L$. Analytically the domain in y expand from $-\infty$ to ∞ . Numerically, we use Dirichlet boundary conditions $y = [0, 2L]$ for pressure.

$$\begin{aligned} v(x = 0, t) &= 1 \\ v(x = 2L, t) &= -1 \\ v(x, 0) &= \begin{cases} 1 & \text{if } x < L, \\ -1 & \text{if } x \geq L. \end{cases} \end{aligned}$$

Analytical solution

∇p is everywhere 0 because the linear combination of a divergence free field is divergence free.

$$\frac{\partial f(x, t)}{\partial t} = \nu \frac{\partial^2 f(x, t)}{\partial x^2} \quad (3.97)$$

We first look for 0 boundary conditions. We will denote this case by f_0 . We first use ansatz that we can separate variable:

$$f_0(x, t) = X(x)T(t) \quad (3.98)$$

The equation then gives:

$$\frac{\dot{T}}{\nu T} = \frac{X''}{X} \quad (3.99)$$

Because the rhs only depends on x and the lhs only depends on t . This needs to depend only on a constant value $-\lambda$. This gives use two uncoupled equations depending on λ .

$$\dot{T} = -\lambda\nu T \quad (3.100)$$

$$X'' = -\lambda X \quad (3.101)$$

The solution for T is:

$$T \propto e^{-\lambda\nu t} \quad (3.102)$$

The solution for X is:

$$X \propto \sin(\sqrt{\lambda}x) \quad (3.103)$$

We only have sin because $\sin(0) = 0$. Because we ask $\sin(2L) = 0$:

$$0 = \sin(2\sqrt{\lambda}L) = \sin\left(n\frac{\pi}{2L}\right) \quad (3.104)$$

This then gives the condition on λ :

$$\sqrt{\lambda} = n\frac{\pi}{2L} \quad (3.105)$$

A linear combination of this for different n is solution too. We found the good linear combination from the Fourier series of the initial condition $f(0, t)$:

$$f_0(x, t) = \sum_{n=1}^{\infty} C_n \sin\left(\frac{n\pi}{2L}x\right) e^{-\frac{n^2\pi^2\nu t}{4L^2}} \quad (3.106)$$

$$C_n = \frac{1}{L} \int_0^{2L} f(x, 0) \sin\left(\frac{n\pi}{2L}x\right) dx \quad (3.107)$$

For a non 0 boundary conditions, we need to add a particular solution, so that $f_p(0, 0) = 1$ and $f_p(2L, 0) = -1$.

$$f_p(x, t) = -\frac{x - L}{L} \quad (3.108)$$

$f_0(x, 0)$ is then given by:

$$f_0(x, 0) = f(x, 0) - f_p(x, t) = \begin{cases} \frac{x}{L} & \text{if } x < L, \\ \frac{x-L}{L} - 1 & \text{if } x \geq L. \end{cases} \quad (3.109)$$

The general solution is then:

$$f(x, t) = -\frac{x - L}{L} + \sum_{n=1}^{\infty} C_n \sin\left(\frac{n\pi}{2L}x\right) e^{-\frac{n^2\pi^2\nu t}{4L^2}} \quad (3.110)$$

$$C_n = \frac{1}{L} \int_0^{2L} f(x, 0) \sin\left(\frac{n\pi}{2L}x\right) dx \quad (3.111)$$

This is plotted for $2L = 0.1$ m and $\nu = 1.307 \cdot 10^{-6}$ Pas which is the viscosity of water for 10°C and for $n_{max} = 1'000'000$ in figure 3.9.

Note that the fact that we have truncated the sum can be considered as a slightly change of initial condition, and an analytical solution of this solution. Numerically the difference is of the level of the numerical precision.

The analytical solution shows that the effect of viscosity is to smooth the speed distribution. The time needed to do that is of 500 s which is a very long time with respect of the distance traveled in this time (500 m). But this doesn't say that viscosity is not important, because it's effect is inversely proportional squared of L .

Numerical solution

We now use our numerical program to solve the same problem. The effective problem that we will solve is the heat equation with as solver Runge-Kutta. The other part of the program as convection and projection are done but should have a negligible effect.

The solution for different times t are shown in figure 3.10, 3.11, 3.12 ,3.13. We have an excellent agreement with the analytical result. For $dt = 2$ s for the Euler method and $dt = 3$ s for the Runge-Kutta method we have divergence (result completely wrong). Note that the time step used is bigger than the CFL condition that is $dt_{max} = hu_{max} = 0.002$ s. This can be done because the viscosity is small and the non linear term cancel.

The solution with low resolution for different time t are shown in figure 3.14, 3.15, 3.16 ,3.17. We are in excellent agreement with this low resolution. The reason can be because the equation is linear.

3.5.2 Oseen vortex decay

Analytical solution

An analytical solution for Navier-Stokes equation without gravity is given in radial coordinate by:

$$v_\theta = \frac{\Gamma}{2\pi r} \left(1 - e^{-\frac{r^2}{4\nu t}} \right) \quad (3.112)$$

$$v_r = 0 \quad (3.113)$$

This can be proven in radial coordinate in the vorticity version of Navier-Stokes equation (not used in this work). In the vorticity version of the equation it consist only of a time derivative and a diffusive term. The convectif term is 0.

The pressure solution can be found inserting the equations 3.112 in Navier-Stokes equations and find ∇p .

We now need to choose a domain and boundary conditions. As domain, we take a circle centered in 0. Because of symetry, the boundary condition for ∇p are constant on the circle. If they weren't we would not have a radial symetry on speed. Constant Dirichlet boundary conditons are then a good boundary condition. The choice of the constant will not change the gradiant.

Numerical result

This problem is interesting for numerical result because we have an simple analytical solution but in radial coordinate and which is found in vortex formulation, this solution is very far away of the cartesian speed pressure formulation used to derive the Navier-Stokes solver.

We use as domain a circle of radius 1 m. We use a viscosity of 1 Pas. We use as boundary conditions for pressure 0 Dirichlet boundary conditons. We use an initial time of $t = 0.01$ because at $t = 0$ the initial conditions have a singularity which will not be fair for the comparison of diffrent grid spacing. N is the radius in cell of the problem. α is the condition so that a particle with the maximun speed of the fluid cannot traverse more of α fraction of a cell.

For speed we use the analytical solution (cf. equations 3.112) outside the domain

Because the analytical solution is radial, it's better to compare in radial coordinate. For this, we do the following, from the numerical solution on staggered grid, we average the speed per cell. Then in the postprocessing stage, we calculate the cartesian analytical on staggered grid and average like for the numerical solution. We then transform the numerical and analytical solution to radial coordinate and compare them.

The result are plotted in figures 3.18 and 3.19.

The first interesting result is that we have no better error when we don't diverge with respect a better time step and better integration method. This is a sign that the error is dominated by the spatial discretization. Only changing the grid spacing change the precision. But a better method and time step gives a better stability.

We see, that the numerical result are not too good and need finner grid to become better. The difficulty in this numerical problem is that the choosen grid is not appropriated to the problem (cartesian grid for a radial problem).

4.1 Introduction

In the previous chapter all numerical schemes were done on the same domain. We will here see the changes that we need to make if we want to have variable topology. We will need to take care of two additional things:

1. Know the speed in cell that weren't in the domain but are in the new time step.
2. Know the position of the different boundary.

We are mainly interested in mobile boundary consisting in free surface boundary because it will be the only boundary that move depending on the solution.

The motion of the domain and the boundary are given by:

$$\dot{\mathbf{x}} = \mathbf{v} \quad (4.1)$$

Where \mathbf{v} is the speed at the given position.

To discretize this equation, we will use particles placed in every cell. A cell where a particle lies is in the domain. A cell without particle is out of the domain. But particles moves with the speed given at there position, which is not on a grid point. Because of this, we need to interpolate the speed at the given point. When a particle moves to a new cell, we need to know the initial speed at this position. We analytically have boundary condition for speed at boundary. We need to extrapolate this boundary condition one cell away.

4.2 Method to obtain an ODE

We can write a non discretized particles method equation as:

$$\begin{aligned}\dot{\mathbf{v}} &= (1 + P(D(\mathbf{x}))) f(\mathbf{v}, \mathbf{x}) \\ \dot{\mathbf{x}} &= \mathbf{v}\end{aligned}$$

Where x are a continuous representation of the space with particle. The notation $P(D(\mathbf{x}))$ says that we consider the projection operator with boundary conditions given by $D(\mathbf{x})$.

We need to add to this boundary conditions, boundary conditions for free surface, that are given by a linear differential operator A .

$$A\mathbf{v} = 0 \quad (4.2)$$

A contains derivative with respect to space but not respect to time.

When we discretize, we will need to interpolate because we need speed at position we don't know (for a staggered grid we have):

$$\begin{aligned}\dot{\mathbf{v}}|_{\in D_v(D(\mathbf{x}))} &= (1 + P(D(\mathbf{x}))) f(E(\mathbf{v}, D_v(D(\mathbf{x}))), D_v(D(\mathbf{x})))|_{\in D_v(D(\mathbf{x}))} \\ \dot{\mathbf{x}} &= I(\mathbf{x}, E(\mathbf{v}, D_v(D(\mathbf{x})))) \\ \mathbf{v}|_{\notin D_v(D(\mathbf{x}))} &= E(\mathbf{v}, D_v(D(\mathbf{x})))|_{\notin D_v(D(\mathbf{x}))}\end{aligned}$$

For mathematical simplicity we will take that \mathbf{v} consists of a speed defined everywhere, but in the computation only speed that are accessed in the time step is needed (only speed in the domain and in it's neighbour). We can model this by considering non used cell with a special value like nan that propagate in every operation.

$D(\mathbf{x})$ indicates the domain in which at least a particle is found. This consist at the same time to the topology for pressure (Pressure is cell centered).

D_v is a function depending on the topology given in general by $D(\mathbf{x})$ and indicate which speed component are in the domain.

f is a function that takes as argument the topology for pressure given by $D(\mathbf{x})$ and the topology for speed given by $D_v(D(\mathbf{x}))$ and the speed everywhere.

E is the extrapolation operator which takes as argument the speed everywhere and returns a speed everywhere, but where the speed in the speed domain is not changed. This speed is the speed that the fluid had if it were there. The distance to which this extrapolation operator needs to give value depend on the choice of the time step. The extrapolation operator needs to take account of two things:

1. The correct boundary conditions.
2. Extrapolate speed farther away than the boundary conditions if a particle moves more than one cell.

I is an interpolation operator which from the speed at discrete position find the speed at a given position.

The use of two topologies is needed because in a staggered grid the position of speed and pressure is not the same.

Remark 4.2.1. *D_v needs to be good chosen to avoid pathological cases. For example for a cell with only one cell. We will normally consider all speed as boundary. But with only boundary we have no speed data. For this reason in this case, we consider all boundary cell as in the domain.*

4.2.1 Splitting

A simple but of only order 1 (in general) mean to solve this equations, is to consider two different problem:

1. Advance speed for a given topology.
2. Advance the particle from the given speed.

The first step is to solve:

$$\dot{\mathbf{v}}|_{\in D_v(D(\mathbf{x}))} = (1 + P(D(\mathbf{x}))) f(E(\mathbf{v}, D_v(D(\mathbf{x}))), D_v(D(\mathbf{x})))|_{\in D_v(D(\mathbf{x}))} \quad (4.3)$$

$$\mathbf{v}_{t_0}|_{\notin D_{v_{t_0}}(D(\mathbf{x}))} = E(\mathbf{v}_{t_0}, D_v(D(\mathbf{x})))|_{\notin D_v(D(\mathbf{x}))} \quad (4.4)$$

Which can be done like in the fixed topology case with a Runge-Kutta method. The second equation indicates the boundary conditions. Numerically we can calculate the speed at boundary at every evaluation of f .

We then move the particles with the calculated speed.

$$\dot{\mathbf{x}} = I(\mathbf{x}, E(\mathbf{v}, D_v(D(\mathbf{x})))) \quad (4.5)$$

This method is only of order 1.

Example 4.2.1. Consider only one particle. With as initial condition 0 speed without viscosity.

The extrapolation operator in this case will copy the speed vertically, the speed will be constant and the only non zero component is in the y direction. The speed will be given by the integration of the gravity force, the convective term is 0 because speed is constant. The speed will be calculated with an accuracy of order of the Runge-Kutta

method used (4 for rk4). But the position will be calculated from the advance of a constant speed for every time step. This is then equivalent to the euler method of order 1.

In final, our speed will be correct at order k for a given time step but position will be wrong.

This error doesn't depend on the precision of integration for the speed or position problem. It comes from the splitting.

4.2.2 One ODE method

We will now show how we can rewrite this differential equation in only one differential equation. For this, we need an expression for the derivative of the boundary condition. When we have it, we only have to use a Runge-Kutta method.

We will now only be interested in the case where E is a linear operator with the two following constraints:

- Its effect for speed in the domain (for speed) is the identity.
- Its effect for speed out of the domain (for speed) depends only on speed of the domain (for speed).

The domain for speed for E is noted $E(D_v(D(\mathbf{x})))$.

In matrix notation it tells us that some blocks need to be 0 or 1. If we consider that indice from 1 to n_d are in the domain (for speed) and $n_d + 1$ to n are out of the domain (for speed), the constraint for a line of the matrix is, using as notation the : as in matlab in indicating by an indice it's position in the vector:

For $i < n_d + 1$

$$E_{i:} = (0 \dots 1_i \dots 0) \quad (4.6)$$

For $i > n_d$

$$E_{i:} = (e_1^i \dots e_{n_d}^i 0 \dots 0) \quad (4.7)$$

$$(4.8)$$

Taking the derivative of $E(D_v(D(\mathbf{x})))\mathbf{v}$ has two terms, the first gives:

$$E(D_v(D(\mathbf{x})))\dot{\mathbf{v}} \quad (4.9)$$

Which uses $\dot{\mathbf{v}}$ but needs it only for the domain because outside the given column of the E matrix is zero.

The second term is the derivative of the matrix E with respect of change of time. Which will lead to the derivative with respect of change of topology. This will give a delta of dirac. The reason of this is because of the discontinuity in time of the boundary speed, when we change topology. We will neglect this dirac delta.

The equation is then:

$$\dot{\mathbf{v}}|_{\in D_v(D(\mathbf{x}))} = (1 + P(D(\mathbf{x}))) f(E(D_v(D(\mathbf{x})))\mathbf{v}, D_v(D(\mathbf{x})))|_{\in D_v(D(\mathbf{x}))} \quad (4.10)$$

$$\dot{\mathbf{v}}|_{\notin D_v(D(\mathbf{x}))} = E(D_v(D(\mathbf{x}))) (1 + P(D(\mathbf{x}))) f(E(D_v(D(\mathbf{x})))\mathbf{v}, D_v(D(\mathbf{x})))|_{\notin D_v(D(\mathbf{x}))} \quad (4.11)$$

$$\mathbf{v}_{t_0}|_{\notin D_{v_{t_0}}(D(\mathbf{x}))} = \left(E(D_v(D(\mathbf{x}))) \mathbf{v}_{t_0}|_{\in D_v(D(\mathbf{x}))} \right)|_{\notin D_v(D(\mathbf{x}))} \quad (4.12)$$

$$\dot{\mathbf{x}} = I(\mathbf{x}, E(D_v(D(\mathbf{x})))\mathbf{v}) \quad (4.13)$$

$$(4.14)$$

Where we have used the notation that vector can be extended with 0 when needed because the extension is not needed because the good columns are zero. Which can be rewritten as:

$$\dot{\mathbf{v}} = E(D_v(D(\mathbf{x}))) (1 + P(D(\mathbf{x}))) f(E(D_v(D(\mathbf{x})))\mathbf{v}, D_v(D(\mathbf{x})))|_{\in D_v(D(\mathbf{x}))} \quad (4.15)$$

$$\mathbf{v}_{t_0}|_{\notin D_{v_{t_0}}(D(\mathbf{x}))} = \left(E(D_v(D(\mathbf{x}))) \mathbf{v}_{t_0}|_{\in D_v(D(\mathbf{x}))} \right)|_{\notin D_v(D(\mathbf{x}))} \quad (4.16)$$

$$\dot{\mathbf{x}} = I(\mathbf{x}, E(D_v(D(\mathbf{x})))\mathbf{v}) \quad (4.17)$$

$$(4.18)$$

Where we have used that E is the identity in the domain. This equation can be integrated with a Runge-Kutta method. For having a maximal precision, the boundary speed is taken from the extrapolation at every complete Runge-Kutta step. In the argument of f we have used an extrapolation of speed which doesn't depends of the input in boundary speed (because the E matrix has zero columns where needed). The integrated boundary speed is only used in the case where a cell become in the domain in a time step.

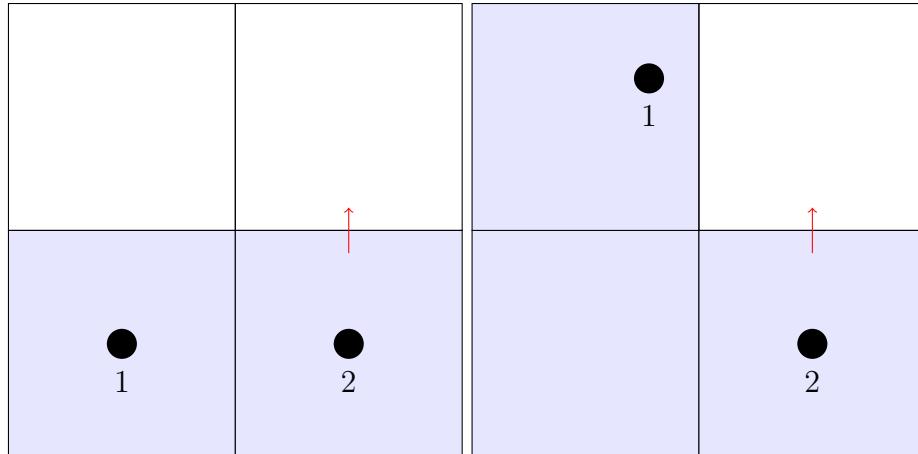

The neglected Dirac delta will only have an effect on a boundary speed component in the case where in a Runge-Kutta step the following happens:

1. A neighbor cell (cell which E matrix has component with) fills. This will change the value of boundary speed with a jump (this jump will be neglected).
2. The given speed is used because a particle fills the domain. This is needed because in the contrary the speed calculated will not be used.

This effect is shown in figure 4.1. This effect will change the precision when it happens from order k to order 1. And this error will only be on the boundary conditions being not exactly respected for a short time. The force will be integrated correctly.

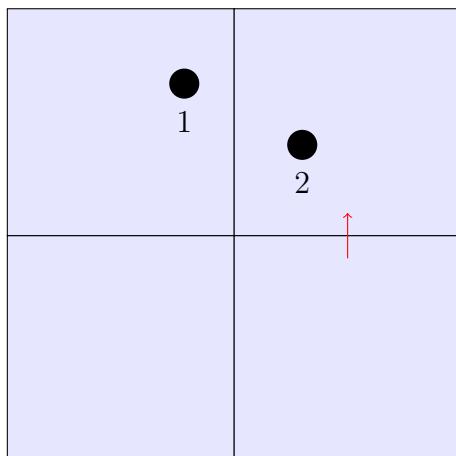

The direct filling of a cell doesn't pose problem because we don't have discontinuity in speed, because in the first region we force speed, in the second the derivative. The jump is only caused because we force speed differently for the two region which give a discontinuity.

Example 4.2.2. *One particle with 0 initial speed, without viscosity. The speed will be constant. So only the gravity force acts and the extrapolation operator will copy speed vertically. The result will then be equivalent to the integration of the purely particle problem where the speed change is calculated at particle position. The order of the method is then k .*

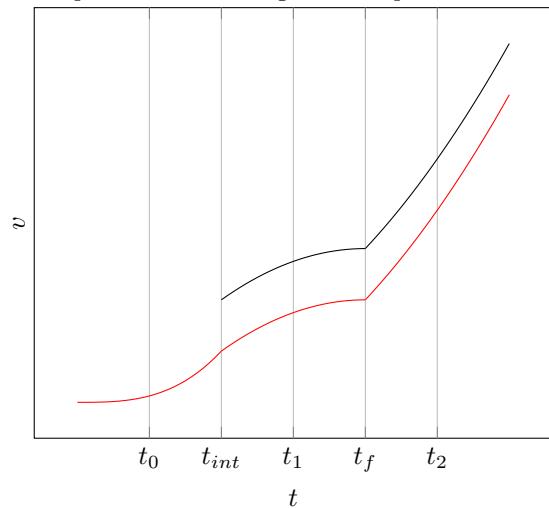

(a) t_0 , the red speed vector is not in the domain and is obtained by extrapolation.

(b) t_1 , because the first particle has moved the domain have changed, the speed extrapolation have changed at red point.

(c) t_2 , because the red point is now in the domain, the speed is given by the acceleration from the Navier-Stokes equations.

(d) Cartoon of speed, the topology at time t_0 , t_1 and t_2 are given in 4.1a , 4.1b and 4.1c. t_{int} is the moment when particle 1 enters in the new cell. t_f is the moment when particle 2 enters in the new cell. The red curve is what we will integrate if we neglect the delta of Dirac, the black curve is the exact result.

Figure 4.1: Figure of the situation where the neglected delta has a effect.

4.3 Extrapolation

We will now discuss how to define the extrapolation operator. We have seen that the extrapolation operator need to do two things:

1. Ensure correct boundary conditions.
2. Extrapolate the rest of speed.

We now are interested in the ensuring of boundary condition. Numerically this will be done in extrapolating the value at exterior from the boundary conditions on the derivative. One important point is how we enforce the boundary conditions in discretized grid. We recall our equation of section 2.3.2:

$$\sum_{i,j} \sigma_{ij} n_i n_j = 0 \quad (4.19)$$

$$\sum_{i,j} \sigma_{ij} t_i^1 n_j = 0 \quad (4.20)$$

$$\sum_{i,j} \sigma_{ij} t_i^2 n_j = 0 \quad (4.21)$$

$$(4.22)$$

Because the constraints are linear, with sufficiently equation and know value we can find an unique solution.

We now will treat the different possible cases in 2d. This will then be generalized in 3d. We will use different discretisation points for pressure and speed. We begin with the discretisation for speed.

4.3.1 2d

Plane

The first case is a surface which is a plane following one of the cell boundary. Without loss of generality we consider the plane in the x direction(the other case are isometric of this case). The normal and tangent vectors are then given by:

$$\mathbf{n} = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad (4.23)$$

$$\mathbf{t} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad (4.24)$$

The equation is then given by:

$$\sum_{i,j} \sigma_{ij} t_i n_j = 0 \quad (4.25)$$

$$\sigma_{12} = 0 \quad (4.26)$$

$$-p\delta_{12} + \nu \left(\frac{\partial v_1}{\partial x_2} + \frac{\partial v_2}{\partial x_1} \right) = 0 \quad (4.27)$$

$$\frac{\partial v_1}{\partial x_2} + \frac{\partial v_2}{\partial x_1} = 0 \quad (4.28)$$

$$(4.29)$$

We discretize this equation at point $i + \frac{1}{2}, j + \frac{1}{2}$:

$$\frac{v_{i+\frac{1}{2},j+1}^1 - v_{i+\frac{1}{2},j}^1}{\Delta x_2} + \frac{v_{i+1,j+\frac{1}{2}}^2 - v_{i,j+\frac{1}{2}}^2}{\Delta x_1} = 0 \quad (4.30)$$

Where Δx_1 and Δx_2 are the spacing in x and y . We have one equation for 3 unknowns, only $v_{i+\frac{1}{2},j}^1$ are known. But we can add two equations using the divergence free condition in the fluid for cell i, j and $i + 1, j$. This gives us:

$$0 = \frac{v_{i+\frac{1}{2},j}^1 - v_{i-\frac{1}{2},j}^1}{\Delta x_1} + \frac{v_{i,j+\frac{1}{2}}^2 - v_{i,j-\frac{1}{2}}^2}{\Delta x_2} \quad (4.31)$$

$$v_{i,j+\frac{1}{2}}^2 = v_{i,j-\frac{1}{2}}^2 - \frac{v_{i+\frac{1}{2},j}^1 - v_{i-\frac{1}{2},j}^1}{\Delta x_1} \Delta x_2 \quad (4.32)$$

$$0 = \frac{v_{i+\frac{3}{2},j}^1 - v_{i+\frac{1}{2},j}^1}{\Delta x_1} + \frac{v_{i+1,j+\frac{1}{2}}^2 - v_{i+1,j-\frac{1}{2}}^2}{\Delta x_2} \quad (4.33)$$

$$v_{i+1,j+\frac{1}{2}}^2 = v_{i+1,j-\frac{1}{2}}^2 - \frac{v_{i+\frac{3}{2},j}^1 - v_{i+\frac{1}{2},j}^1}{\Delta x_1} \Delta x_2 \quad (4.34)$$

We substitute the two equations 4.32 and 4.34 in equation 4.30. Which will now only depend on one unknown $v_{i+\frac{1}{2},j+1}^1$ which depends on quantity that can be found using the speed in the domain. Figure 4.2 shows the variables used and which are substitute from other.

We can only do the things that we have done only if we have a depth of minimal two cells. If we have only one cell, we have no y speed in the domain of calculation. For this case, consider the speed y at boundary as in the domain and let it evolve without constraint.

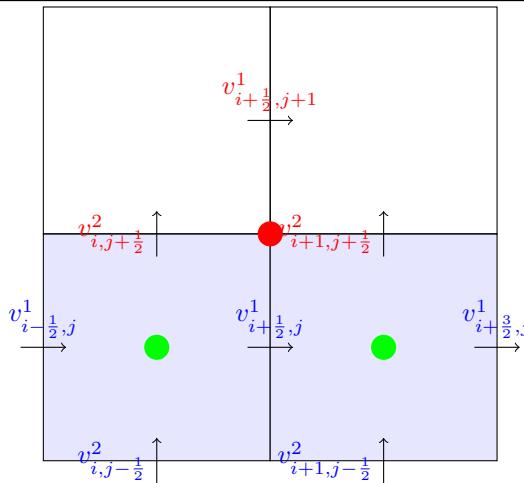

Figure 4.2: The red point is the place where the boundary conditions is discretized. The green dots are cells where the divergence free rule is enforced. Red vector are calculated with respect of the blue one.

45° plane

If we have a cell in domain with two adjacent cells which are not in the domain. We take as normal a 45° plane.

The normal and tangent vectors are then:

$$\mathbf{n} = \begin{pmatrix} \frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} \end{pmatrix} \quad (4.35)$$

$$\mathbf{t} = \begin{pmatrix} \frac{\sqrt{2}}{2} \\ -\frac{\sqrt{2}}{2} \\ -\frac{\sqrt{2}}{2} \end{pmatrix} \quad (4.36)$$

The constraint is given by:

$$\sum_{ij} \sigma_{ij} n_i t_j = 0 \quad (4.37)$$

$$\sigma_{11} n_1 t_1 + \sigma_{22} n_2 t_2 + \sigma_{12} (n_1 t_2 + n_2 t_1) = 0 \quad (4.38)$$

$$2 \frac{\partial v_1}{\partial x_1} \frac{1}{2} - 2 \frac{\partial v_2}{\partial x_2} \frac{1}{2} = 0 \quad (4.39)$$

$$\frac{\partial v_1}{\partial x_1} - \frac{\partial v_2}{\partial x_2} = 0 \quad (4.40)$$

We discretize at cell center i, j which gives:

$$\frac{v_{i+\frac{1}{2},j}^1 - v_{i-\frac{1}{2},j}^1}{\Delta x_1} - \frac{v_{i,j+\frac{1}{2}}^2 - v_{i,j-\frac{1}{2}}^2}{\Delta x_2} = 0 \quad (4.41)$$

We have two unknowns $v_{i+\frac{1}{2},j}^1$ and $v_{i,j+\frac{1}{2}}^2$. We add an additional equation using the divergence free condition at cell i, j :

$$\frac{v_{i+\frac{1}{2},j}^1 - v_{i-\frac{1}{2},j}^1}{\Delta x_1} + \frac{v_{i,j+\frac{1}{2}}^2 - v_{i,j-\frac{1}{2}}^2}{\Delta x_2} = 0 \quad (4.42)$$

Figure 4.3 shows the position of variables and their elimination.

For this to work, we need to have the left and below boundary speed to be known. The boundary needs to be like that because in the contrary we will have no data in the x or y directions.

4.3.2 3d

The method used in 2d is generalized to 3d. The only change will be that the expressions are more complicate, and that we have more variables. The two cases that we have seen in 2d will be similar for the 2d variable but with added dependency in the z variable.

Plane

The first case is a surface which is a plane following one of the cell boundary. Without loss of generality we consider the plane in the x and z directions. The normal and

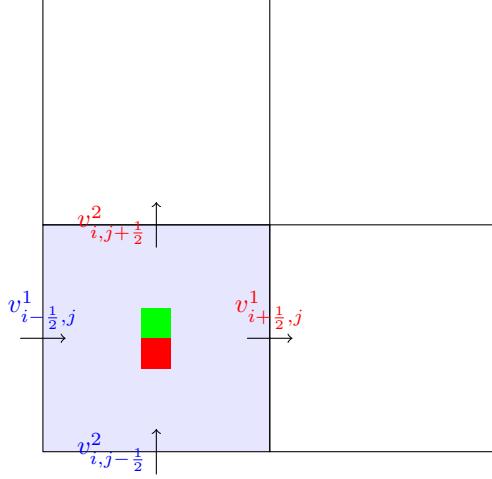

Figure 4.3: The red green rectangles are the place where the boundary equation and divergence equation are used. Red vector are expressed with respect of blue one.

tangent vectors are then given by:

$$\mathbf{n} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \quad (4.43)$$

$$\mathbf{t}^1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad (4.44)$$

$$\mathbf{t}^2 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \quad (4.45)$$

The equations are then given by:

For \mathbf{t}^1

$$\sum_{i,j} \sigma_{ij} t_i^1 n_j = 0 \quad (4.46)$$

$$\sigma_{12} = 0 \quad (4.47)$$

$$-p\delta_{12} + \nu \left(\frac{\partial v_1}{\partial x_2} + \frac{\partial v_2}{\partial x_1} \right) = 0 \quad (4.48)$$

$$\frac{\partial v_1}{\partial x_2} + \frac{\partial v_2}{\partial x_1} = 0 \quad (4.49)$$

For t^2

$$\sum_{i,j} \sigma_{ij} t_i^2 n_j = 0 \quad (4.50)$$

$$\sigma_{32} = 0 \quad (4.51)$$

$$-p\delta_{32} + \nu \left(\frac{\partial v_3}{\partial x_2} + \frac{\partial v_2}{\partial x_3} \right) = 0 \quad (4.52)$$

$$\frac{\partial v_3}{\partial x_2} + \frac{\partial v_2}{\partial x_3} = 0 \quad (4.53)$$

We discretize equation 4.49 at point $i + \frac{1}{2}, j + \frac{1}{2}, k$:

$$\frac{v_{i+\frac{1}{2},j+1,k}^1 - v_{i+\frac{1}{2},j,k+\frac{1}{2}}^1}{\Delta x_2} + \frac{v_{i+1,j+\frac{1}{2},k}^2 - v_{i,j+\frac{1}{2},k}^2}{\Delta x_1} = 0 \quad (4.54)$$

We discretize equation 4.53 at point $i, j + \frac{1}{2}, k + \frac{1}{2}$:

$$\frac{v_{i,j+1,k+\frac{1}{2}}^3 - v_{i,j,k+\frac{1}{2}}^3}{\Delta x_2} + \frac{v_{i,j+\frac{1}{2},k+1}^2 - v_{i,j+\frac{1}{2},k}^2}{\Delta x_3} = 0 \quad (4.55)$$

Where Δx_1 , Δx_2 and Δx_3 are the spacing in x , y and z . We have 2 equations for 5 unknowns, only $v_{i+\frac{1}{2},j,k}^1$ and $v_{i,j,k+\frac{1}{2}}^3$ are known. But we can add 3 equations using the divergence free condition in the fluid for cell i, j, k , $i + 1, j, k$ and $i, j, k + 1$. This gives us:

$$0 = \frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} + \frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} + \frac{v_{i,j,k+\frac{1}{2}}^3 - v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} \quad (4.56)$$

$$v_{i,j+\frac{1}{2},k}^2 = v_{i,j-\frac{1}{2},k}^2 + \Delta x_2 \left(-\frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} - \frac{v_{i,j,k+\frac{1}{2}}^3 - v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} \right) \quad (4.57)$$

$$0 = \frac{v_{i+\frac{3}{2},j,k}^1 - v_{i+\frac{1}{2},j,k}^1}{\Delta x_1} + \frac{v_{i+1,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} + \frac{v_{i+\frac{1}{2},j,k+\frac{1}{2}}^3 - v_{i+\frac{1}{2},j,k-\frac{1}{2}}^3}{\Delta x_3} \quad (4.58)$$

$$v_{i+1,j+\frac{1}{2},k}^2 = v_{i+1,j-\frac{1}{2},k}^2 + \Delta x_2 \left(-\frac{v_{i+\frac{3}{2},j,k}^1 - v_{i+\frac{1}{2},j,k}^1}{\Delta x_1} - \frac{v_{i+\frac{1}{2},j,k+\frac{1}{2}}^3 - v_{i+\frac{1}{2},j,k-\frac{1}{2}}^3}{\Delta x_3} \right) \quad (4.59)$$

$$0 = \frac{v_{i+\frac{1}{2},j,k+1}^1 - v_{i-\frac{1}{2},j,k+1}^1}{\Delta x_1} + \frac{v_{i,j+\frac{1}{2},k+1}^2 - v_{i,j-\frac{1}{2},k+1}^2}{\Delta x_2} + \frac{v_{i,j,k+\frac{3}{2}}^3 - v_{i,j,k+\frac{1}{2}}^3}{\Delta x_3} \quad (4.60)$$

$$v_{i,j+\frac{1}{2},k+1}^2 = v_{i,j-\frac{1}{2},k+1}^2 + \Delta x_2 \left(-\frac{v_{i+\frac{1}{2},j,k+1}^1 - v_{i-\frac{1}{2},j,k+1}^1}{\Delta x_1} - \frac{v_{i,j,k+\frac{3}{2}}^3 - v_{i,j,k+\frac{1}{2}}^3}{\Delta x_3} \right) \quad (4.61)$$

$$(4.62)$$

We substitute the equations 4.57, 4.59 and 4.61 in equations 4.54 and 4.55. Which will now only depend on two unknowns $v_{i+\frac{1}{2},j+1,k}^1$ and $v_{i,j+1,k+\frac{1}{2}}^3$ which depends on quantity that can be found using the speed in the domain.

We can only do what we have done only if we have a depth of minimal two cells. If we have only one cell, we have no y speed in the domain in calculation. For this case, consider the speed y at boundary as in the domain.

45° plane

If we have a cell in domain with two adjacent cells which are not in the domain. We take as normal a 45° plane. The normal and tangent vectors are then:

$$\mathbf{n} = \begin{pmatrix} \frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} \\ 0 \end{pmatrix} \quad (4.63)$$

$$\mathbf{t}^1 = \begin{pmatrix} \frac{\sqrt{2}}{2} \\ -\frac{\sqrt{2}}{2} \\ 0 \end{pmatrix} \quad (4.64)$$

$$\mathbf{t}^2 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \quad (4.65)$$

The constraints are given by:

For \mathbf{t}^1

$$\sum_{ij} \sigma_{ij} n_i t_j^1 = 0 \quad (4.66)$$

$$\sigma_{11} n_1 t_1^1 + \sigma_{22} n_2 t_2^1 + \sigma_{12} (n_1 t_2^1 + n_2 t_1^1) = 0 \quad (4.67)$$

$$2 \frac{\partial v_1}{\partial x_1} \frac{1}{2} - 2 \frac{\partial v_2}{\partial x_2} \frac{1}{2} = 0 \quad (4.68)$$

$$\frac{\partial v_1}{\partial x_1} - \frac{\partial v_2}{\partial x_2} = 0 \quad (4.69)$$

For \mathbf{t}^2

$$\sum_{ij} \sigma_{ij} n_i t_j^2 = 0 \quad (4.70)$$

$$\sigma_{13} n_1 t_3^2 + \sigma_{23} n_2 t_3^2 = 0 \quad (4.71)$$

$$\frac{\partial v_1}{\partial x_3} + \frac{\partial v_3}{\partial x_1} + \frac{\partial v_2}{\partial x_3} + \frac{\partial v_3}{\partial x_2} = 0 \quad (4.72)$$

In this case, we are able to solve equation 4.69. We discretize at cell center i, j, k which gives:

$$\frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} - \frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} = 0 \quad (4.73)$$

We have two unknowns $v_{i+\frac{1}{2},j}^1$ and $v_{i,j+\frac{1}{2}}^2$. We add an additional equation using the divergence free condition at cell i, j, k :

$$\frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} + \frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} + \frac{v_{i,j,k+\frac{1}{2}}^3 - v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} = 0 \quad (4.74)$$

If we want to be exact, we will need to consider in this equation $v_{i,j,k+\frac{1}{2}}^3$ and $v_{i,j,k-\frac{1}{2}}^3$ as unknown and try to determine them from equation 4.72. But a good discretisation will need to use speed outside of the cell. Which will lead to a recursif solving.

A first approximation is to ignore equation 4.72 and consider $v_{i,j,k+\frac{1}{2}}^3$ and $v_{i,j,k-\frac{1}{2}}^3$ as known.

For this to work, we need to have the left and below boundary speed to be known. The boundary needs to be like that because in the contrary we will have no data in the x or y directions.

Diagonal slopped plane

We now look a really 3d case, where the plane is diagonal on the 3 axis. The normal and tangent vectors are:

$$\mathbf{n} = \begin{pmatrix} \frac{\sqrt{3}}{3} \\ \frac{\sqrt{3}}{3} \\ \frac{\sqrt{3}}{3} \end{pmatrix} \quad (4.75)$$

$$\mathbf{t}^1 = \begin{pmatrix} -\frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} \\ 0 \end{pmatrix} \quad (4.76)$$

$$\mathbf{t}^2 = \begin{pmatrix} 0 \\ \frac{\sqrt{2}}{2} \\ -\frac{\sqrt{2}}{2} \end{pmatrix} \quad (4.77)$$

The constraints are then:

For \mathbf{t}^1

$$0 = \sum_{ij} \sigma_{ij} n_i t_j^1 \quad (4.78)$$

$$0 = \sigma_{11} n_1 t_1^1 + \sigma_{12} n_1 t_2^1 + \sigma_{21} n_2 t_1^1 + \sigma_{22} n_2 t_2^1 + \sigma_{31} n_3 t_1^1 + \sigma_{32} n_3 t_2^1 \quad (4.79)$$

using that $t_1^1 = -t_2^1$ and $\sigma_{ij} = \sigma_{ji}$

$$0 = n_1 t_1^1 (\sigma_{11} - \sigma_{12}) + n_2 t_1^1 (\sigma_{21} - \sigma_{22}) + n_3 t_1^1 (\sigma_{31} - \sigma_{32}) \quad (4.80)$$

using that $n_1 = n_2 = n_3$

$$0 = \sigma_{11} - \sigma_{12} + \sigma_{21} - \sigma_{22} + \sigma_{31} - \sigma_{32} \quad (4.81)$$

$$0 = 2 \frac{\partial u_1}{\partial x_1} - 2 \frac{\partial u_2}{\partial x_2} + \frac{\partial u_3}{\partial x_1} + \frac{\partial u_1}{\partial x_3} - \frac{\partial u_3}{\partial x_2} - \frac{\partial u_2}{\partial x_3} \quad (4.82)$$

For \mathbf{t}^2

$$0 = \sum_{ij} \sigma_{ij} n_i t_j^2 \quad (4.83)$$

$$0 = \sigma_{13} n_1 t_3^2 + \sigma_{12} n_1 t_2^2 + \sigma_{23} n_2 t_3^2 + \sigma_{22} n_2 t_2^2 + \sigma_{33} n_3 t_3^2 + \sigma_{32} n_3 t_2^2 \quad (4.84)$$

using that $t_2^2 = -t_3^2$ and $\sigma_{ij} = \sigma_{ji}$

$$0 = n_1 t_3^2 (\sigma_{13} - \sigma_{12}) + n_2 t_3^2 (\sigma_{23} - \sigma_{22}) + n_3 t_3^2 (\sigma_{33} - \sigma_{32}) \quad (4.85)$$

using that $n_1 = n_2 = n_3$

$$0 = \sigma_{13} - \sigma_{12} + \sigma_{23} - \sigma_{22} + \sigma_{33} - \sigma_{32} \quad (4.86)$$

$$0 = 2\frac{\partial u_3}{\partial x_3} - 2\frac{\partial u_2}{\partial x_2} + \frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1} - \frac{\partial u_1}{\partial x_2} - \frac{\partial u_2}{\partial x_1} \quad (4.87)$$

We discretize equation 4.82 at position i, j, k :

$$\begin{aligned} 0 = & 2\frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} - 2\frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} \\ & + \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i-1,j,k+\frac{1}{2}}^3 - v_{i-1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\ & + \frac{v_{i+\frac{1}{2},j,k}^1 + v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-1}^1 - v_{i-\frac{1}{2},j,k-1}^1}{2\Delta x_3} \\ & - \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i,j-1,k+\frac{1}{2}}^3 - v_{i,j-1,k-\frac{1}{2}}^3}{2\Delta x_2} \\ & - \frac{v_{i,j+\frac{1}{2},k}^2 + v_{i,j-\frac{1}{2},k}^2 - v_{i,j+\frac{1}{2},k-1}^2 - v_{i,j-\frac{1}{2},k-1}^2}{2\Delta x_3} \end{aligned} \quad (4.88)$$

We discretize equation 4.87 at position i, j, k :

$$\begin{aligned} 0 = & 2\frac{v_{i,j,k+\frac{1}{2}}^3 - v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} - 2\frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} \\ & + \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i-1,j,k+\frac{1}{2}}^3 - v_{i-1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\ & + \frac{v_{i+\frac{1}{2},j,k}^1 + v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-1}^1 - v_{i-\frac{1}{2},j,k-1}^1}{2\Delta x_3} \\ & - \frac{v_{i,j,k+\frac{1}{2}}^1 + v_{i,j,k-\frac{1}{2}}^1 - v_{i,j+1,k+\frac{1}{2}}^1 - v_{i,j-1,k-\frac{1}{2}}^1}{2\Delta x_2} \\ & - \frac{v_{i,j+\frac{1}{2},k}^2 + v_{i,j-\frac{1}{2},k}^2 - v_{i-1,j+\frac{1}{2},k}^2 - v_{i-1,j-\frac{1}{2},k}^2}{2\Delta x_1} \end{aligned} \quad (4.89)$$

The unknowns are $v_{i+\frac{1}{2},j,k}^1$, $v_{i,j+\frac{1}{2},k}^2$ and $v_{i,j,k+\frac{1}{2}}^3$. The last equation is given by the divergence free condition at cell i, j, k :

$$0 = \frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} + \frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} + \frac{v_{i,j,k+\frac{1}{2}}^3 - v_{i,j,k+\frac{1}{2}}^3}{\Delta x_3} \quad (4.90)$$

Contrary to the other case we have not a direct method to solve by substitution. We will rewrite the equation as:

$$A \begin{pmatrix} v_{i+\frac{1}{2},j,k}^1 \\ v_{i,j+\frac{1}{2},k}^2 \\ v_{i,j,k+\frac{1}{2}}^3 \end{pmatrix} = b \quad (4.91)$$

b_3 is given by equation 4.90:

$$b_3 = \frac{v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} + \frac{v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} + \frac{v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} \quad (4.92)$$

b_2 is given by equation 4.109:

$$\begin{aligned} b_2 = & 2 \frac{v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} - 2s_2 \frac{v_{i,j-s_2\frac{1}{2},k}^2}{\Delta x_2} - \frac{v_{i,j,k-\frac{1}{2}}^3 - v_{i-1,j,k+\frac{1}{2}}^3 - v_{i-1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\ & - \frac{v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-1}^1 - v_{i-\frac{1}{2},j,k-1}^1}{2\Delta x_3} + \frac{v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j-1,k}^1 - v_{i-\frac{1}{2},j-1,k}^1}{2\Delta x_2} \\ & + \frac{v_{i,j-\frac{1}{2},k}^2 - v_{i-1,j+\frac{1}{2},k}^2 - v_{i-1,j-\frac{1}{2},k}^2}{2\Delta x_1} \end{aligned} \quad (4.93)$$

b_1 is given by equation 4.108:

$$\begin{aligned} b_1 = & 2 \frac{v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} - 2 \frac{v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} - \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i-1,j,k+\frac{1}{2}}^3 - v_{i-1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\ & - \frac{v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-1}^1 - v_{i-\frac{1}{2},j,k-1}^1}{2\Delta x_3} + \frac{v_{i,j,k-\frac{1}{2}}^3 - v_{i,j-1,k+\frac{1}{2}}^3 - v_{i,j-1,k-\frac{1}{2}}^3}{2\Delta x_2} \\ & + \frac{v_{i,j-\frac{1}{2},k}^2 - v_{i,j+\frac{1}{2},k-1}^2 - v_{i,j-\frac{1}{2},k-1}^2}{2\Delta x_1} \end{aligned} \quad (4.94)$$

The matrix A is then:

$$A = \begin{pmatrix} \frac{2}{\Delta x_1} + \frac{1}{2\Delta x_3} & -\frac{2}{\Delta x_2} - \frac{1}{2\Delta x_3} & \frac{1}{2\Delta x_1} - \frac{1}{2\Delta x_2} \\ \frac{1}{2\Delta x_3} - \frac{1}{2\Delta x_2} & -\frac{1}{\Delta x_2} - \frac{1}{2\Delta x_1} & \frac{1}{\Delta x_3} + \frac{1}{2\Delta x_1} \\ \frac{1}{\Delta x_1} & \frac{1}{\Delta x_2} & \frac{1}{\Delta x_3} \end{pmatrix} \quad (4.95)$$

This matrix only depend on the spacing so it can be calculated at initialization.

The general case is:

$$\mathbf{n} = \begin{pmatrix} \frac{s_1\sqrt{3}}{3} \\ \frac{s_2\sqrt{3}}{3} \\ \frac{s_3\sqrt{3}}{3} \end{pmatrix} \quad (4.96)$$

$$\mathbf{t}^1 = \begin{pmatrix} -s_1\frac{\sqrt{2}}{2} \\ s_2\frac{\sqrt{2}}{2} \\ 0 \end{pmatrix} \quad (4.97)$$

$$\mathbf{t}^2 = \begin{pmatrix} 0 \\ s_2\frac{\sqrt{2}}{2} \\ -s_3\frac{\sqrt{2}}{2} \end{pmatrix} \quad (4.98)$$

The constraints are then:

For t^1

$$0 = \sum_{ij} \sigma_{ij} n_i t_j^1 \quad (4.99)$$

$$0 = \frac{\sqrt{6}}{6} (-\sigma_{11} + \sigma_{12}s_1s_2 - \sigma_{21}s_1s_2 + \sigma_{22} - \sigma_{31}s_3s_1 + \sigma_{32}s_3s_2) \quad (4.100)$$

$$0 = -\sigma_{11} + \sigma_{22} - \sigma_{31}s_3s_1 + \sigma_{32}s_3s_2 \quad (4.101)$$

$$0 = -2 \frac{\partial u_1}{\partial x_1} + 2 \frac{\partial u_2}{\partial x_2} - s_3s_1 \frac{\partial u_3}{\partial x_1} - s_3s_1 \frac{\partial u_1}{\partial x_3} + s_3s_2 \frac{\partial u_3}{\partial x_2} + s_3s_2 \frac{\partial u_2}{\partial x_3} \quad (4.102)$$

For t^2

$$0 = \sum_{ij} \sigma_{ij} n_i t_j^2 \quad (4.103)$$

$$0 = \frac{\sqrt{6}}{6} (-\sigma_{13}s_1s_3 + \sigma_{12}s_1s_2 - \sigma_{23}s_2s_3 + \sigma_{22} - \sigma_{33} + \sigma_{32}s_3s_2) \quad (4.104)$$

$$0 = \frac{\sqrt{6}}{6} (-\sigma_{13}s_1s_3 + \sigma_{12}s_1s_2 + \sigma_{22} - \sigma_{33}) \quad (4.105)$$

$$0 = -\sigma_{13}s_1s_3 + \sigma_{12}s_1s_2 + \sigma_{22} - \sigma_{33} \quad (4.106)$$

$$0 = -2 \frac{\partial u_3}{\partial x_3} + 2 \frac{\partial u_2}{\partial x_2} - s_1s_3 \frac{\partial u_1}{\partial x_3} - s_1s_3 \frac{\partial u_3}{\partial x_1} + s_1s_2 \frac{\partial u_1}{\partial x_2} + s_2s_1 \frac{\partial u_2}{\partial x_1} \quad (4.107)$$

We discretize equation 4.102 at position i, j, k :

$$\begin{aligned} 0 = & -2 \frac{v_{i+\frac{1}{2},j,k}^1 - v_{i-\frac{1}{2},j,k}^1}{\Delta x_1} + 2 \frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} \\ & - s_3 \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i-s_1,j,k+\frac{1}{2}}^3 - v_{i-s_1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\ & - s_1 \frac{v_{i+\frac{1}{2},j,k}^1 + v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-s_3}^1 - v_{i-\frac{1}{2},j,k-s_3}^1}{2\Delta x_3} \\ & + s_3 \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i,j-s_2,k+\frac{1}{2}}^3 - v_{i,j-s_2,k-\frac{1}{2}}^3}{2\Delta x_2} \\ & + s_2 \frac{v_{i,j+\frac{1}{2},k}^2 + v_{i,j-\frac{1}{2},k}^2 - v_{i,j+\frac{1}{2},k-s_3}^2 - v_{i,j-\frac{1}{2},k-s_3}^2}{2\Delta x_3} \end{aligned} \quad (4.108)$$

We discretize equation 4.107 at position i, j, k :

$$\begin{aligned}
 0 = & -2 \frac{v_{i,j,k+\frac{1}{2}}^3 - v_{i,j,k-\frac{1}{2}}^3}{\Delta x_3} + 2 \frac{v_{i,j+\frac{1}{2},k}^2 - v_{i,j-\frac{1}{2},k}^2}{\Delta x_2} \\
 & - s_3 \frac{v_{i,j,k+\frac{1}{2}}^3 + v_{i,j,k-\frac{1}{2}}^3 - v_{i-s_1,j,k+\frac{1}{2}}^3 - v_{i-s_1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\
 & - s_1 \frac{v_{i+\frac{1}{2},j,k}^1 + v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-s_3}^1 - v_{i-\frac{1}{2},j,k-s_3}^1}{2\Delta x_3} \\
 & + s_1 \frac{v_{i+\frac{1}{2},j,k}^1 + v_{i-\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j-s_2,k}^1 - v_{i-\frac{1}{2},j-s_2,k}^1}{2\Delta x_2} \\
 & + s_2 \frac{v_{i,j+\frac{1}{2},k}^2 + v_{i,j-\frac{1}{2},k}^2 - v_{i-s_1,j+\frac{1}{2},k}^2 - v_{i-s_1,j-\frac{1}{2},k}^2}{2\Delta x_1}
 \end{aligned} \tag{4.109}$$

The unknowns are $v_{i+s_1\frac{1}{2},j,k}^1$, $v_{i,j+s_2\frac{1}{2},k}^2$ and $v_{i,j,k+s_3\frac{1}{2}}^3$.

We can write it by matrix form:

$$A \begin{pmatrix} v_{i+s_1\frac{1}{2},j,k}^1 \\ v_{i,j+s_2\frac{1}{2},k}^2 \\ v_{i,j,k+s_3\frac{1}{2}}^3 \end{pmatrix} = b \tag{4.110}$$

b_3 is given by equation 4.90:

$$b_3 = s_1 \frac{v_{i-s_1\frac{1}{2},j,k}^1}{\Delta x_1} + s_2 \frac{v_{i,j-s_2\frac{1}{2},k}^2}{\Delta x_2} + s_3 \frac{v_{i,j,k-s_3\frac{1}{2}}^3}{\Delta x_3} \tag{4.111}$$

b_2 is given by:

$$\begin{aligned}
 b_2 = & -2s_3 \frac{v_{i,j,k-s_3\frac{1}{2}}^3}{\Delta x_3} + 2s_2 \frac{v_{i,j-s_2\frac{1}{2},k}^2}{\Delta x_2} + s_3 \frac{v_{i,j,k-s_3\frac{1}{2}}^3 - v_{i-s_1,j,k+\frac{1}{2}}^3 - v_{i-s_1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\
 & + s_1 \frac{v_{i-s_1\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-s_3}^1 - v_{i-\frac{1}{2},j,k-s_3}^1}{2\Delta x_3} - s_1 \frac{v_{i-s_1\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j-s_2,k}^1 - v_{i-\frac{1}{2},j-s_2,k}^1}{2\Delta x_2} \\
 & - s_2 \frac{v_{i,j-s_2\frac{1}{2},k}^2 - v_{i-s_1,j+\frac{1}{2},k}^2 - v_{i-s_1,j-\frac{1}{2},k}^2}{2\Delta x_1}
 \end{aligned} \tag{4.112}$$

b_1 is given by:

$$\begin{aligned}
 b_1 = & -2s_1 \frac{v_{i-s_1\frac{1}{2},j,k}^1}{\Delta x_1} + 2s_2 \frac{v_{i,j-s_2\frac{1}{2},k}^2}{\Delta x_2} + s_3 \frac{v_{i,j,k-s_3\frac{1}{2}}^3 - v_{i-s_1,j,k+\frac{1}{2}}^3 - v_{i-s_1,j,k-\frac{1}{2}}^3}{2\Delta x_1} \\
 & + s_1 \frac{v_{i-s_1\frac{1}{2},j,k}^1 - v_{i+\frac{1}{2},j,k-s_3}^1 - v_{i-\frac{1}{2},j,k-s_3}^1}{2\Delta x_3} - s_3 \frac{v_{i,j,k-s_3\frac{1}{2}}^3 - v_{i,j-s_2,k+\frac{1}{2}}^3 - v_{i,j-s_2,k-\frac{1}{2}}^3}{2\Delta x_2} \\
 & - s_2 \frac{v_{i,j-s_2\frac{1}{2},k}^2 - v_{i,j+\frac{1}{2},k-s_3}^2 - v_{i,j-\frac{1}{2},k-s_3}^2}{2\Delta x_3}
 \end{aligned} \tag{4.113}$$

The matrix A is then:

$$A = \begin{pmatrix} -s_1 \frac{2}{\Delta x_1} - s_1 \frac{1}{2\Delta x_3} & s_2 \frac{2}{\Delta x_2} + s_2 \frac{1}{2\Delta x_3} & -s_3 \frac{1}{2\Delta x_1} + s_3 \frac{1}{2\Delta x_2} \\ -s_1 \frac{1}{2\Delta x_3} + s_1 \frac{1}{2\Delta x_2} & s_2 \frac{2}{\Delta x_2} + s_2 \frac{1}{2\Delta x_1} & -s_3 \frac{2}{\Delta x_3} - s_3 \frac{1}{2\Delta x_1} \\ s_1 \frac{1}{\Delta x_1} & s_2 \frac{1}{\Delta x_2} & s_3 \frac{1}{\Delta x_3} \end{pmatrix} \quad (4.114)$$

4.3.3 Other case

With the different cases seen above, we cannot treat all cases. Two things can happen.

1. We are too thin (only one cell), in this case we consider the boundary speed as in the domain, because we need at least 2 speeds of same component in a given direction to be able to make calculation.
2. We have a succession of plane and diagonal cells. But the plane cells are not sufficiently long to use the above case. Or other case that cannot be decomposed in the above case. In this case we extrapolate unknown speed from the mean of the neighboring speed in the same speed component. We then evenly distribute the divergence to the unknown speed to be divergence free.

This technique allows to define a speed to every bound of a cell in the domain.

We will then need to extrapolate it further away with a technique shown in the next section. If a speed that is not directly at boundary is defined it will be protected from erasure for the next stage (an implementation technique for this is to put a nan value in unknown).

4.3.4 Pressure boundary conditions

The pressure boundary conditions are applied in cell outside of the domain. The condition comes from the study from a plane of only one cell. For example for normal of:

$$\mathbf{n} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad (4.115)$$

The equations are:

$$0 = \sigma_{11} n_1 = -p + 2\nu \frac{\partial v_1}{\partial x_1} \quad (4.116)$$

$$p = 2\nu \frac{\partial v_1}{\partial x_1} \quad (4.117)$$

Which in using the boundary speed found from the extrapolation and boundary conditions gives:

$$p = 2\nu \frac{v_{i+\frac{1}{2},j}^1 - v_{i,j}^1}{\Delta x_1} \quad (4.118)$$

In general we can be neighbor of more than one of these cases. In this case we sum the given pressure.

4.3.5 Extrapolate further away

We now need to extrapolate further away to be able to use bigger time steps. And for some pathological case motion where the boundary conditions need speed that were not in the boundary condition at step before. The following method can be used:

For every not known speed, average from known speeds that are nearer from a surface of fluid.

This is done by implementing first a notion of “Layer” which indicates the distance from the fluid for a given cell. The extrapolation is then done layer by layer using only value of layer before.

The exact code is a little complicated because of the staggered grid which brings a little asymmetry in choosing which cell layer need to be used (a speed component is between 2 cell).

4.4 Interpolation

For interpolation, we don't have constraint on the scheme. A simple one can for example be n -linear interpolation. The only thing to take care is that we are in a staggered grid so that known speeds are not at the same place for all components.

4.4.1 n -linear

A n linear interpolation is a non linear interpolation but a product of linear interpolation so that in every direction the interpolation is linear.

For 1d it's given for c_1 and c_2 the value at x_1 and x_2 by:

$$f(x, y) = c_2 \frac{x - x_1}{x_2 - x_1} + c_1 \frac{x - x_2}{x_1 - x_2} \quad (4.119)$$

For 2d it's given by:

$$f(x, y) = c_{11} \frac{x - x_2}{x_1 - x_2} \frac{y - y_2}{y_1 - y_2} + c_{12} \frac{x - x_1}{x_1 - x_2} \frac{y - y_1}{y_2 - y_1} + c_{21} \frac{x - x_1}{x_2 - x_1} \frac{y - y_2}{y_1 - y_2} + c_{22} \frac{x - x_2}{x_1 - x_2} \frac{y - y_1}{y_1 - y_2} \quad (4.120)$$

For 3d it's calculated similarly.

4.5 Pseudo code

We will now give pseudo code to augment the program seen in the previous chapter.

4.5.1 Data type

In addition to data type that we have seen in the previous chapter. We add the following data type.

Layer: layers are integer stored in the cell which indicates the distance from the fluid.

Two methods are defined. A method to set (**LayerSet**) and a method to get (**LayerGet**). A special value of -1 is used for indicating empty cells. This is used in the initialization algorithm before considering which values the layer have.

Depth: Depths are integer stored in the cell which indicates the depth in the fluid.

This is used for optimization of the number of particle. Particles are only used near the surface. Not deep inside the fluid. Two methods are defined. A method to set (**DepthSet**) and a method to get (**DepthGet**). A special value of -1 is used for indicating empty cell

Particle: We need a list of particle which consist only of list of position. A method (**CellGet()**) that transforms a particle in the cell which it lays in is needed. This method can be written in term of rounding after a scaling so that cell spacing are 1. Method to add and remove particle of the list are needed. The order in the list is not relevant we only need to be able to remove a particle in an arbitrary position in the list.

Interior: A special cell type, interior cell is used. Interior cells are considered as cell fluid, but where the method **GetIsInterior** return true. Interior cells are cell which don't need to have fluid particle in there. The only mean to remove an interior cell is to "Remove" the fluid cell around it.

4.5.2 Initialisation

Overview

In this part we need to do the following:

- From the position of the particle determine which cell is fluid.
- Add particle in inflow cell.
- Create air cell around the fluid to store extrapolation data.
- Create a variable named layer which has value 0 in the fluid and the distance from the fluid in air cell. This is used in extrapolation method.

This part is the only part that creates cells or creates particles. The difficulty of this part is that we have value that are not updated or do not exist. Order of the algorithm are very important.

To do this we use the following step:

1. We initialize a variable called layer on every cell to a value of -1 .
2. We put layer to 0 for cell with a particle in it and set the cell type to fluid.
3. We create particle in inflow if needed.
4. We iteratively set layer away from surface and set air cell.
5. We delete cell with layer of -1 .

Because of compression and for optimization of number of particle we use another variable called depth. This variable indicate the depth in fluid from the surface. Cell which are bigger than a certain depth are interior cell. Interior cells are considered as fluid cells but which don't need particle in there. Particles are created from a certain depth in cell to allow compression effect which will deform the sampling of particle. To have only particles at the surface allows to have more particles at the surface with the

same performance. This is important in 3d flow where the number of particle increase with h^3 if we put particle everywhere. We can do this mathematically because an opening in the fluid can only happen when we have a discontinuity in speed. This discontinuity can be detected in the speed on the grid.

Initialize layer and depth

This algorithm initialize the layer of every cell to -1 so that we can set the layer to 0 of cells which have particle in it. For depth we only consider celld which are in the exterior fluid cells and don't touch interior cell so that they have the maximal depth of the preceding iteration. This is shown in algorithm 14

Algorithm 14 Algorithm which Initialize the layer and depth.

```

1: procedure INITIALIZELAYERANDDEPTH
2:   for all  $it \in Grid$  do
3:      $it.\text{LayerSet}(-1)$             $\triangleright$  We set layer to -1 so that other method can fill the layer.
4:     if  $it.\text{GetIsFluid}()$  and not( $it.\text{GetIsInterior}()$ ) then  $\triangleright$  These are fluid cells at exterior.
5:        $it.\text{DepthSet}(-1)$             $\triangleright$  We set their depth to -1 to initialize.
6:     end if
7:   end for
8: end procedure
```

Initialize layer with particle and depth

This algorithm will use the position of the particles to set the layer where the particles are to 0. It will also delete particles that are at interior more than a given depth because particle are not needed there. This can be seen in algorithm 15

Algorithm 15 Algorithm which initialize layer and depth from the particles.

```

1: procedure LAYERINITIALWITHPARTICLEDEPTH
2:   for all  $it \in Particles$  do                                 $\triangleright$  We loop for all particle
3:      $cell \leftarrow it.\text{CellGet}()$   $\triangleright$  Use of the particle position to know which cell the particle lies in.
4:     if  $cell.\text{GetIsInterior}()$  then
5:        $cell.\text{LayerSet}(0)$ 
6:       if  $cell.\text{DepthGet}() > depmax$  then       $\triangleright$  The particle is at interior of more than a
certain depth.
7:          $Particles.\text{erase}(it)$                        $\triangleright$  We erase it.
8:       end if
9:     else
10:       $cell.\text{LayerSetLayer}(0)$ 
11:       $cell.\text{FluidSet}()$             $\triangleright$  We set to fluid cells because a particle lies in this position.
12:    end if
13:  end for
14: end procedure
```

Create fluid particle depth

This algorithm creates particle if needed and force that interior cells are filled. New particles are needed if:

1. It's a inbound cell which has no particle in it (has layer -1) which represent a source of fluid of the physical problem.
2. It's a interior cell which has depth smaller than the limit to remove particle.

The need of interior cell are for two reasons:

1. Performance optimization because at interior the only mean to not be fluid is by a discontinuity on the speed. This discontinuity can be found on the speed on grid. So we don't need particle at interior.
2. By deformation of the fluid the sampling of fluid can be insufficient and air cell can manifest because we have no sufficient particle. It allow to have a bigger number of particle by cell to be more resistant to deformation effect only where it's needed, at the surface. Particle are created in the interior region if needed to go in the surface region to add sampling.

The algorithm is shown in algorithm 16. The method **InboundNeedFilling** and **AddParticle** need to be defined. The first tests if we are an empty inbound cell. The second will create one or more particles in the cell.

An identique algorithm without creation of particle named **CreateInteriorDepth** is used (cf. algorithm 17) when we are in a Runge-Kutta step and don't want to create new particles because vectors will no more have the same length which is problematic for a Runge-Kutta method.

Algorithm 16 Algorithm which creates new particles if needed and set that interior are always filled.

```

1: procedure LAYERINITIALWITHPARTICLEDEPTH
2:   for all  $it \in Grid$  do
3:     if InboundNeedFilling( $it$ ) then                                 $\triangleright$  We need filling.
4:       AddParticle( $it$ )
5:        $it$ .LayerSet(0)
6:        $it$ .FluidSet()
7:     else if  $it$ .GetIsInterior() and  $it$ .LayerGet() =  $-1$  and  $it$ .DepthGet()  $\leq depthmax$ 
8:     then                                          $\triangleright$  We are an interior cell which is near the surface and is empty. Create a particle.
9:       AddParticle( $it$ )
10:       $it$ .LayerSet(0)
11:    else if  $it$ .GetIsInterior() then  $\triangleright$  Interior cells always have a layer of 0. Because they are
12:      considered as fluid.
13:       $it$ .LayerSet(0)
14:    end if
15:  end for
16: end procedure

```

Update cellType layer depth

We now need to create the layer variable and depth variable and create air cell around the fluid. We do this recursively beginning from the fluid and avancing neighbour by neighbour.

This is done in 3 parts. First algorithm 18 create the first list with boundary cell. Then algorithm 19 create the layer moving away from the fluid. At the contrary algorithm 20 create the depth moving in the fluid from the surface.

Algorithm 17 Algorithm which set layer to 0 if needed but doesn't creates particles and set that interior are always filled.

```

1: procedure CREATEINTERIORDEPTH
2:   for all  $it \in Grid$  do
3:     if InboundNeedFilling( $it$ ) then                                 $\triangleright$  We need filling.
4:        $it$ .LayerSet(0)
5:        $it$ .FluidSet()
6:     else if  $it$ .GetIsInterior() then       $\triangleright$  Interior fluid always have a 0 layer. No particle is
       created.
7:        $it$ .LayerSet(0)
8:     end if
9:   end for
10: end procedure

```

Algorithm 18 Algorithm which creates the first layer list with cells at the boundary.

```

1: procedure UPDATECELLTYPELAYERDEPTH
2:    $stack \leftarrow newunorderedstack()$ 
3:   for all  $it \in Grid$  do
4:      $it$ .DepthSet(-1)                                          $\triangleright$  Every cell begin with a depth of -1
5:      $b \leftarrow false$ 
6:     if  $it$ .LayerGet() = 0 then
7:       for  $i = 1$  to  $dim$  do
8:         if not( $b$ ) then                                      $\triangleright b$  is a boolean used to indicate the need to exit.
9:           for  $si = \pm 1$  do
10:              $it2 \leftarrow it$ .GetNeighbour( $i, si$ )
11:             if not( $it2$ .IsValid()) or  $it2$ .LayerGet() = -1 then       $\triangleright$  If neighbor cell
                  doesn't exist or has an empty layer, this is a sign of a non fluid cell.
12:                $it$ .DepthSet(0)
13:                $stack$ .insert( $it$ )                                      $\triangleright$  Insert in  $stack$  the current cell.
14:                $b \leftarrow true$   $\triangleright$  We have added in  $stack$  so that we need not to reprocess this
                  cell. This will only insert more than one time this cell.
15:               break
16:             end if
17:           end for
18:         end if
19:       end for
20:     end if
21:   end for

```

Algorithm 19 Algorithm which use the first list to create layer recursively away from the surface.

```

22:   stackbackup ← stack      ▷ We backup the stack, this is needed because in depth part we will
   need the same stack.
23:   for lay = 1 to laymax do
24:     stack2 ← newunorderedstack()      ▷ Stack that will be filled with the next candidate.
25:     for all cell ∈ stack do          ▷ We loop in all cell in the stack.
26:       for i = 1 to dim do
27:         for si = ±1 do
28:           cell2 ← it. GetNeighbour(i, si)
29:           if not(cell2. IsValid()) or cell2. LayerGet() = -1 then ▷ We redo the test if
   the neighbour cell is air or none existent.
30:             cell. Set(i, it. Get(i) + si)
31:             cell. CreateCell()          ▷ We create the neighbour cell to be able to add
   information in it.
32:             cell. LayerSet(lay)        ▷ We set the layer of the new cell.
33:             cell. AirSet()            ▷ The new cell is an air cell.
34:             stack2.insert(it) ▷ We insert the new cell in the new stack because as new
   cell it's a candidate for new air.
35:             cell. Set(i, it. Get(i) - si)
36:           end if
37:         end for
38:       end for
39:     end for
40:     stack ← stack2                  ▷ The new list becomes the current list.
41:   end for
42:   for all cell ∈ Stack do ▷ A last loop to move in the positif direction because of the asymetry
   in speed.
43:     for i = 1 to dim do
44:       cell2 ← cell. GetNeighbour(i, 1)
45:       if not(cell2. IsValid()) or cell2. LayerGet() = -1 then
46:         cell. Set(i, it. Get(i) + si)
47:         cell. CreateCell()
48:         cell. LayerSet(laymax + 1)
49:         cell. AirSet()
50:         cell. Set(i, it. Get(i) - si)
51:       end if
52:     end for
53:   end for

```

Algorithm 20 Algorithm which uses the first list to create depth recursively in from the surface.

```

54:   depth  $\leftarrow 1$                                       $\triangleright$  The depth is 1.
55:   loop
56:     stack2  $\leftarrow \text{newunorderedstack}()$        $\triangleright$  New stack that we will fill with candidate cell.
57:     for all cell  $\in \text{stackbackup}$  do           $\triangleright$  We use the stackbackup because it contains at first
        iteration the content after the first step.
58:       for i = 1 to dim do
59:         for si $\pm$  do
60:           cell2  $\leftarrow \text{cell. GetNeighbour}(i, si)$ 
61:           if cell2.LayerGet() = 0 and cell2.DepthGet() = -1 then  $\triangleright$  If the neighbour
             is fluid and has depth of -1.
62:             cell.Set(i, cell.Get(i) + si)
63:             cell.LayerSet(0)
64:             cell.DepthSet(depth)
65:             if depth < interiordepth then  $\triangleright$  If the depth is smaller than the limit we set
               the cell as fluid cell.
66:               cell.FluidSet()
67:             else
68:               cell.InteriorSet()  $\triangleright$  If the depth is bigger than the limit we set the cell
               as interior.
69:             end if
70:             stack2.insert(it)                          $\triangleright$  We add the cell in the list.
71:             cell.Set(i, cell.Get(i) - si)
72:           end if
73:         end for
74:       end for
75:     end for
76:     stackbackup  $\leftarrow \text{stack2}$                    $\triangleright$  The new list becomes the current list.
77:     if stackbackup.empty() then  $\triangleright$  If the new list is empty we have ended. It's the only way
       to exit the loop.
78:       break
79:     end if
80:   end loop
81: end procedure

```

Delete macCell

We delete cells that have layer of -1 because they are cells that are not fluid and not in the air layer around fluid. Retain cell with layer of -1 will not change the mathematics. They will only be dead weight. This is shown in algorithm 21.

Algorithm 21 Algorithm to delete cell if layer is -1 .

```

1: procedure DELETEMACCELL
2:   for all  $it \in Grid$  do
3:     if  $it.\text{LayerGet}() = -1$  then
4:        $Grid.\text{erase}(it)$ 
5:     end if
6:   end for
7: end procedure
```

Calculate time step

We calculate the optimum time step. The optimum time step is given so that a particle move a maximum of a given fraction of a cell. This is shown in algorithm 22

Algorithm 22 Calculates the optimum time step.

```

1: procedure CALCULATETIMESTEP max=0;
2:   for all  $it \in Grid$  do            $\triangleright$  We calculate the maximum speed weighted from the spacing.
3:     if  $it.\text{GetIsFluid}()$  then
4:        $vtemp \leftarrow 0$ 
5:       for  $i = 1$  to  $dim$  do           $\triangleright$  Calculation of norm 2 of speed weighted with spacing.
6:          $vtemp \leftarrow vtemp + (it.\text{SpeedGet}(i) \cdot h.\text{Get}(i))^2$ 
7:       end for
8:       if  $vtemp > max$  then       $\triangleright$  If we are bigger than actual maximum, we have a new
maximun.
9:          $max \leftarrow vtemp$ 
10:      end if
11:    end if
12:  end for
13:   $dt \leftarrow \frac{factor}{\sqrt{max}}$             $\triangleright$  New candidate time step.
14:   $dt \leftarrow \text{CheckDT}(dt)$             $\triangleright$  We check the time step (min, max checking for example).
15: end procedure
```

conclusion

We now have all the algorithms to initialize the topology. We note that all these steps only involve integer calculation, this allows the compiler to do extensive optimization to simplify calculation.

We have two different initialization cases:

1. Complete initialization done before a Runge-Kutta step. We create particle and calculate the optimum time step.
2. Partial initialization done in a Runge-Kutta step. We don't create particle and don't change time step. But the rest is the same as a complete initialization step.

Algorithm 23 Complete initialization

```

1: procedure INITIALIZATION
2:   InitializeLayerAndDepth()
3:   LayerInitialWithParticleDepth()
4:   UpdateCellTypeLayerDepth()
5:   DeleteMacCell()
6:   CalculateTimeStep()
7: end procedure

```

Algorithm 24 Complete initialization

```

1: procedure INITIALIZATIONRUNGEKUTTA
2:   InitializeLayerAndDepth()
3:   CreateInteriorDepth()
4:   UpdateCellTypeLayerDepth()
5:   DeleteMacCell()
6: end procedure

```

The two algorithms are shown in algorithms 23 and 24.

We will now consider extrapolation method.

4.5.3 Boundary conditions extrapolation

Overview

The following steps are needed to determine boundary conditions in 2d:

1. Mark all speed between air cell to **nan**.
2. Find boundary cell: Fluid cells that are neighbor of air cell.
3. Choose which case of section 4.3.1 and apply it. If we cannot use a case we mark the speed with **nan**.
4. Extrapolate boundary speeds which are **nan** and correct divergence.

Extreme care need to be taken to only use known speed. Topology is very important for this part.

Speed in domain

A speed component is in the domain if its two neighbor cells are in the domain or we are too thin. The function take 2 arguments, a cell and a direction and return a boolean. This pseudo code assumes that all cells exist and are fluid or not fluid. In the real code the existence of the cell must be checked.

Boundary between fluid and air

We now need to know when a fluid cell is a boundary between fluid and air, and extract information of which direction is the boundary. As input, we take the cell which we are interested in. As output a boolean if we are a boundary, and 2 arrays where we return every direction and sign of the interface. The value *n* indicates how many interface we have. This is shown in algorithm 26.

Algorithm 25 Algorithm to find if a speed component is in the domain or not.

```

1: function GETISPEEDINDOMAIN(speed, dir)▷ speed is the position of the cell, dir the direction
2:   speed2  $\leftarrow$  speed.GetNeighbour(dir, -1) ▷ speed2 is now the other cell touching the given
   speed component.
3:   if speed.GetIsFluid() and speed2.GetIsFluid() then
4:     return true ▷ We are between 2 fluid cells, we are in the domain.
5:   end if
6:   if not(SPEED.GETISFLUID()) and not(SPEED2.GETISFLUID()) then
7:     return false ▷ We are between 2 non fluid cells, we are out the domain.
8:   end if
9:   ▷ Now one of speed or speed2 is fluid. speed3 is the cell at the other side of the fluid cell.
10:  if speed.GetIsFluid() then
11:    speed3  $\leftarrow$  speed.GetNeighbour(dir, 1) ▷ Because speed is fluid speed3 is the other side
   of speed than speed2
12:   else if speed2.GetIsFluid() then
13:     speed3  $\leftarrow$  speed2.GetNeighbour(dir, -1) ▷ Because speed2 is fluid speed3 is the other
   side of speed2 than speed
14:   end if
15:   if not(speed3.GetIsFluid) then
16:     return true▷ We are in a thin fluid case, because we have 2 neighbor air cells speed3 and
   one of speed2 or speed
17:   end if
18:   return false
19: end function

```

Algorithm 26 Algorithm to find if a fluid cell is a neighbor of air cell. And have a list of interface.

```

1: function ISBOUNDARY(cell, dir[2 * dim], sign[2 * dim], n) ▷
   dim is the space dimension,cell is the position of the cell, dir and sign are two arrays which will
   be filled for every fluid air interface will indicate the direction and the sign toward the air. n is
   the number of interface and the number of element filled in the array.
2:   if cell.GetIsAir() then
3:     return false ▷ We are an air cell so we are not fluid.
4:   end if
5:   n  $\leftarrow$  0
6:   for i = 1 to dim do ▷ For every direction.
7:     for s =  $\pm 1$  do ▷ For every sign.
8:       dir[n]  $\leftarrow$  i ▷ We store the actual direction (it will be override if n is not incremented).
9:       sign[n]  $\leftarrow$  s ▷ We store the actual sign (it will be override if n is not incremented).
10:      cell2  $\leftarrow$  Cell.GetNeighbour(i, s)
11:      if cell2.IsValid() then
12:        if cell2.GetIsAir() then
13:          n  $\leftarrow$  n + 1 ▷ We have found an interface increase the number of currently
   found interface. The dir and sign arrays have an entry for them that will not be erased because
   we have increased n.
14:        end if
15:      end if
16:    end for
17:  end for
18:  if n > 0 then
19:    return true ▷ We have at least one interface, we are a boundary.
20:  end if
21:  return false ▷ We have no interface, we are not boundary.
22: end function

```

Choose boundary case

We are now able to detect boundary cell. We now need to recognize the different cases. For this we use the information on the number of neighbor and which neighbor:

- If we have one neighbour we are candidate for a plane case. We need then to try every neighbor along the surface to see if it has the same interface with same direction.
- If we have two neighbor interfaces of different components, we are in a diagonal plane case. This case is the more easy because we don't need to verify other thing.
- If it's not possible we put **nan** in the given component to know for the rest of the algorithm that this speed is not known.

The application of plane rules is given in section 4.3.1. This is shown in algorithm 27.

Apply 2D plane

To Apply the 2d plane rule we do the following thing:

1. We use the divergence free condition 2 times for 3 known speeds and one unknown.
2. We use the last equation 4.30 to find the last unknown.

The divergence part equation is shown in algorithm 28. The plane part is shown in algorithm 29.

Apply 2d 45° plane

In the 45° we simply copy the speed from the opposite known speed component. This is shown in algorithm 30.

Apply set nan

We need to set to **nan** all speed component that are not boundary with a fluid cell. This are speed component between two air cells. The **nan** value will be used in the extrapolation method after to know which speeds are unknow. This is shown in algorithm 31.

Nan extrapolation

We have cells with **nan** at booundary, and need to extrapolate a speed in the **nan** in respecting the divergence free condition. For this, we to do the following for every cell.

1. We remember the position of **nan** value.
2. We extrapolate a speed in **nan** value.
3. We calculate the divergence in the cell.
4. We distribute the divergence to all **nan** value.

Algorithm 27 Algorithm that finds in which boundary case we are.

```

1: function CHOOSEBOUNDARYCASE2D(cell, dir[2dim], sign[2dim], n) ▷ cell is the position of the
   cell, dir, sign and n are the same as IsBoundary(cell, dir, sign, n)
2:   if n = 1 then ▷ Only one interface this is a candidate for a horizontal or vertical plane case.
3:     dir2  $\leftarrow$  1
4:     if dir[0] = 1 then
5:       dir2  $\leftarrow$  2 ▷ dir2 is now the tangent direction.
6:     end if
7:     b = true
8:     for s =  $\pm 1$  do ▷ For every sign.
9:       cell2  $\leftarrow$  cell.GetNeighbour(dir2, s)
10:      IsBoundary(cell2, dirtemp, signtemp, ntemp) ▷ We see the interface type of the two
        neighbor cells.
11:      if ntemp = 1 and dirtemp[0] = dir[0] then ▷ If we are again a candidate for a
        horizontal or a vertical plane case.
12:        b  $\leftarrow$  false ▷ Set b to indicate that we were able to have a plane with at least one
        direction.
13:        if i < 0 then ▷ We change the order of the worker cell depending of the sign (will
        be useful later to calculate derivative)
14:          Apply2dPlane(cell2, cell, dir[0], sign[0])
15:        else if i > 0 then ▷ If the two function calls are called, the speed at cell normal to
        the surface, will be changed two times but with the same expression.
16:          Apply2dPlane(cell, cell2, dir[0], sign[0])
17:        end if
18:      end if
19:    end for
20:    if b then
21:      cell3  $\leftarrow$  cell
22:      if sign[0] = 1 then
23:        cell3  $\leftarrow$  cell.GetNeighbour(dir[0], 1) ▷ Depending on the sign, we need to look
        the cell below because of the staggered grid.
24:      end if
25:      if not(GetIsSpeedInDomain(cell, dir[0])) then
26:        cell3.SpeedSet(dir[0], nan) ▷ If we don't consider the given speed as in the
        domain we set it to nan so that a later algorithm can set it to another value.
27:      end if
28:    end if
29:    else if n = 2 then ▷ We have two neighbors, we are candidate for a oblic plane case.
30:      if dir[0]  $\neq$  dir[1] then ▷ We test if we are oblic.
31:        sa  $\leftarrow$  sign[0] ▷ We store the two sign.
32:        sb  $\leftarrow$  sign[1]
33:        if dir[0] > dir[1] then ▷ We reorder the sign in increasing order.
34:          sa  $\leftarrow$  sign[1]
35:          sb  $\leftarrow$  sign[0]
36:        end if
37:        Apply2dPlane45(cell, sa, sb) ▷ We apply the oblic case.
38:      end if
39:    else ▷ We have none of the known case.
40:      for i = 0 to n do ▷ For every direction where we have an interface.
41:        cell2  $\leftarrow$  cell
42:        if sign[i] = 1 then
43:          cell2  $\leftarrow$  cell.GetNeighbour(dir[i], 1) ▷ Because we are in a staggered grid
        depending of the sign we take the neighbour.
44:          end if
45:          if not(GetIsSpeedInDomain(cell2, dir[i])) then ▷ If we are not a boundary speed.
46:            cell2.SpeedSet(dir[i], nan) ▷ We set the speed to nan so that later method can
            change it.
47:          end if
48:        end for
49:      end if
50:    end function

```

Algorithm 28 Algorithm to calculate the speed at a given point from the divergence free condition.

```

1: function APPLYDIV2D(cell, dir, sign)           ▷ cell is the cell were to calculate divergence.
   dir and sign indicate which of the 4 speed components we want to calculate.dir is the direction,
   sign is +1 for the right or above component and -1 for the left and below.
2:   cell2 ← cell.GetNeighbour(dir, 1)      ▷ cell2 will be the cell where the unknown speed
   component lays.
3:   v ← cell.SpeedGet(dir)      ▷ v is the known speed component at opposite of the unknown.
4:   if sign = -1 then                      ▷ Depending of the sign we need to take other cell.
5:     v ← cell2.SpeedGet(dir)
6:     cell2 ← cell
7:   end if
8:   dir2 ← 1                                ▷ dir2 is the other direction than dir
9:   if dir = 1 then
10:    dir2 ← 2
11:   end if
12:   v2 ← cell.SpeedGet(dir2)          ▷ Speed value of the first known speed.
13:   v3 ← cell.GetNeighbour(dir2, 1).SpeedGet(dir2)      ▷ Speed value of the second known
   speed opposite to the first.
14:   res ← v - sign  $\frac{h. \text{Get}(dir)}{h. \text{Get}(dir2)}$  (v3 - v2) ▷ Solution from the divergence free condition to find one
   unknown from 3 known speeds.
15:   cell2.SpeedSet(dir, res)            ▷ Set the new known speed
16: end function

```

Algorithm 29 Algorithm to apply the calculation of a 2d plane case.

```

1: function APPLY2DPLANE(cell, cell2, dir, sign)           ▷ cell and cell2 are two cells in fluid
   marking the plane boundary. cell and cell2 are given in increasing order in the normal direction
   of dir. dir and sign indicate the direction of Air.
2:   ApplyDiv2d(cell, dir, sign)    ▷ We use the divergence condition to find the 4bpspeed from 3
   known.
3:   ApplyDiv2d(cell2, dir, sign)  ▷ We use the divergence condition to find the 4bpspeed from 3
   known.
4:   dir2 ← 1
5:   if dir = 1 then
6:     dir2 ← 2                                ▷ dir2 is now the tangent direction.
7:   end if
8:   v1 ← cell.SpeedGet(dir)
9:   v2 ← cell2.SpeedGet(dir)
10:  v3 ← cell2.SpeedGet(dir2)
11:  v ← - $\frac{sign}{h. \text{Get}(dir2)}$  h. Get(dir) (v2 - v1) + v3      ▷ This is equation 4.30 with other notation.
12:  cell3 ← cell2.GetNeighbour(dir, sign)
13:  cell3.SpeedSet(dir2, v)                ▷ We set the new speed.
14: end function

```

Algorithm 30 Algorithm to apply the 45° plane case

```

1: function APPLY2DPLANE45(cell ,sa,sb)
2:   v1  $\leftarrow$  cell.SpeedGet(1)                                 $\triangleright v1$  is the known speed in direction 1.
3:   v2  $\leftarrow$  cell.SpeedGet(2)                                 $\triangleright v2$  is the known speed in direction 2.
4:   n1  $\leftarrow$  cell.GetNeighbour(1, 1)       $\triangleright n1$  is the cell of the unknown speed in direction 1.
5:   n2  $\leftarrow$  cell.GetNeighbour(2, 1)       $\triangleright n2$  is the cell of the unknown speed in direction 2.
6:   if sa $=-1$  then  $\triangleright$  If the sign in the first direction is different, we change the expression for v1
    and n1.
7:     v1  $\leftarrow$  cell.GetNeighbour(1, 1).SpeedGet(1)
8:     n1  $\leftarrow$  cell
9:   end if
10:  if sb $=-1$  then  $\triangleright$  If the sign in the second direction is different, we change the expression for
    v2 and n2.
11:    v2  $\leftarrow$  cell.GetNeighbour(2, 1).SpeedGet(2)
12:    n2  $\leftarrow$  neigh
13:  end if
14:  n1.SpeedSet(1,v1)           $\triangleright$  In the oblic case, we simply copy the speed in opposite direction.
15:  n2.SpeedSet(2,v2)           $\triangleright$  In the oblic case, we simply copy the speed in opposite direction.
16: end function

```

Algorithm 31 Algorithm that sets speed component between air cell to **nan**.

```

1: function APPLYSETNAN(cell)
2:   if cell.GetIsFluid() then                                 $\triangleright$  We only work on air cell.
3:     return
4:   end if
5:   for i = 1 to dim do                                 $\triangleright$  For every direction
6:     for s =  $\pm 1$  do                                 $\triangleright$  For every sign
7:       cell2  $\leftarrow$  cell.GetNeighbour(i, s);
8:       if cell2.IsValid() then
9:         if neigh2.GetIsAir() then           $\triangleright$  We look that we are between two air cells
10:          cell3  $\leftarrow$  cell2                 $\triangleright$  We set cell3 to the cell with the speed component.
11:          if s $=-1$  then
12:            cell3  $\leftarrow$  cell
13:          end if
14:          cell3.SpeedSet(i, nan)           $\triangleright$  We set the speed to nan
15:        end if
16:        else if s $=-1$  then  $\triangleright$  If we have no neighbour in this direction when s $=-1$  we will
    have a speed component with only a cell in one side.
17:          cell.SpeedSet(i, nan)
18:        end if
19:      end for
20:    end for
21: end function

```

The important point that makes that we have existence and unicity of a solution. Is that we cannot have a **nan** value which has no non **nan** neighbour. This is the case because if this happens we consider the given speed component as in the domain. For example the single fluid cell case. Could make this case if we consider the 4 speeds as out of the domain. We have no known speed to extrapolate with. But our conditions are so that in this case we consider the 4 speeds as in the domain. This is shown in Algorithm 32 and 33.

Do 2d

We now put all our pieces together. For every cell we do the following operation:

1. We set to **nan** speed components that are between two air cells. We need to do it at the beginning because some cases are able to calculate this component, in this case we have no extrapolation because the **nan** value will become a none **nan** value.
2. We treat the known boundary condition case.
3. We extrapolate the speed for the **nan** value at boundary but in having a divergence free speed.

We need to do each step in a separate foreach because we have dependance on the foreach before. But we have no dependance between the same foreach. A foreach can be called in parallel, if we ensure that concurrent write at the same speed component of the same value give the given value and not garbage. And if we ensure that we can get and set speed concurrently on different speed component without problem.

Note that in all this foreach loop we do not change the speed component number, only their value. A simple fixed matrix implementation will respect all this condition.

This is shown in algorithm 34.

Conclusion

In conclusion, we have an algorithm of linear complexity (only one level of nested for each) which can be possibly parallelizable.

This algorithm is specialized for boundary condition in straight plane and in corner. For the other case an extrapolation scheme is used. If more accurate boundary conditions are needed, the given case can be added in the choose section.

4.5.4 Extrapolation

We now need to extrapolate **nan** value from known value which is nearer from the surface. This is done iteratively layer by layer. Exact pseudo code is a little complicate because of the staggered grid. For details look the algorithm 35 , 36 and 37. And the figure given in comment.

4.5.5 Interpolation

We will now show the pseudo code for interpolation for N dimension with N -linear interpolation. The principal difficulty is that on a staggered grid the position of know speed vary for all component. The algorithm needed to do the translation is shown in algorithm 39. The interpolation is shown in algorithm 38.

Algorithm 32 Algorithm that extrapolates **nan** speed component in the boundary (first part).

```

1: function APPLYNANEXTRAP(cell)
2:   n  $\leftarrow$  0
3:   for i = 1 to dim do                                 $\triangleright$  For every direction
4:     v1  $\leftarrow$  cell.SpeedGet(i)
5:     cell_temp  $\leftarrow$  cell.GetNeighbour(i, 1)
6:     v2  $\leftarrow$  cell_temp.SpeedGet(i)
7:     if v1 = nan then  $\triangleright$  We are nan, we stock the direction and sign in tab, where we have a
      vector of vector with 0 the direction 1 the sign.
8:       tab[0][n]  $\leftarrow$  i
9:       tab[1][n]  $\leftarrow$  0
10:       $+ + n$ 
11:    end if
12:    if v2 = nan then  $\triangleright$  We are nan, we stock the direction and sign in tab, where we have a
      vector of vector with 0 the direction 1 the sign.
13:      tab[0][n]  $\leftarrow$  i
14:      tab[1][n]  $\leftarrow$  1
15:       $+ + n$ 
16:    end if
17:  end for
18:  if n = 0 then                                 $\triangleright$  We have no nan nothing to do. return
19:  end if
20:  for i = 0 to n do                       $\triangleright$  For every nan. We set the nan value from extrapolation.
21:    dir  $\leftarrow$  tab[0][i]
22:    sign  $\leftarrow$  tab[1][i]
23:    cell2  $\leftarrow$  cell
24:    if sign = 1 then
25:      cell2  $\leftarrow$  cell.GetNeighbour(dir, 1)
26:    end if
27:    vtemp  $\leftarrow$  0
28:    nb  $\leftarrow$  0
29:    for dir2 = 1 to dim do                 $\triangleright$  We look all directions.
30:      for s =  $\pm 1$  do                       $\triangleright$  We look all signs.
31:        add  $\leftarrow$  cell2.SpeedGet(dir)           $\triangleright$  We get the speed value.
32:        if add  $\neq$  nan then                   $\triangleright$  If it's not nan we add it.

21:    end if
22:  end for
23:  cell  $\leftarrow$  Grid[key]                                               $\triangleright$  We get the cell at the calculated key.
24:  ret.Set(k, GetSpeedImpl(posdelta2, 1, cell, k))       $\triangleright$  We call the interpolation routine and
   set the result in the return vector.
25:  posdelta.Set(k, posdelta.Get(k) – 0.5)
26:  end for
27:  return ret
28: end function

```

4.5.6 Integration

For the non splitted case the acceleration is given by 4.15. We use to avoid to rewrite a extrapolation fonction a method **SetSpeedToAcceleration(bool)** which toggle that the method to set the speed and get the speed act on acceleration instead. This is shown in algorithm 40

We now integrate with the Runge-Kutta method, the difference with respect to the case in section 3.4.4 is that we now have particle. We need to do the same that we have done having a copy of all particle position. This is shown in algorithm 41 and 42.

A complete iteration consist of Algorithm 43

Algorithm 40 Calculate the acceleration for the non splitted method equation 4.15.

4.6 Numerical experiment

4.6.1 One particle fall

We have discussed this case qualitatively we will now simulated it numerically.

We take as initial condition a single particle with 0 speed everywhere without viscosity falling from gravity.

The analytical solution is for the continuous problem given by:

$$v = -gt \quad (4.121)$$

$$x = x_0 - \frac{1}{2}gt^2 \quad (4.122)$$

If we add viscosity the same is true.

Result

We see in figure 4.7 that the non splitted method coincide with the analytical solution for as integration method Runge-Kutta of order 4. The reason is that the analytical solution is a polynomial of order 2.

At the contrary because of the splitting a splitting method will incorrectly approximate the result, because it's of order 1 at general.

When we have big time step like $\alpha = 2$ non splitted method behave better. But it's important to recall the result on fixed grid, that having a too big time step make diverge.

4.6.2 Lateral jet

We consider a continuous source of speed in the x direction. With gravity at the y direction. The analytical solution can be found without consideration of the boundary

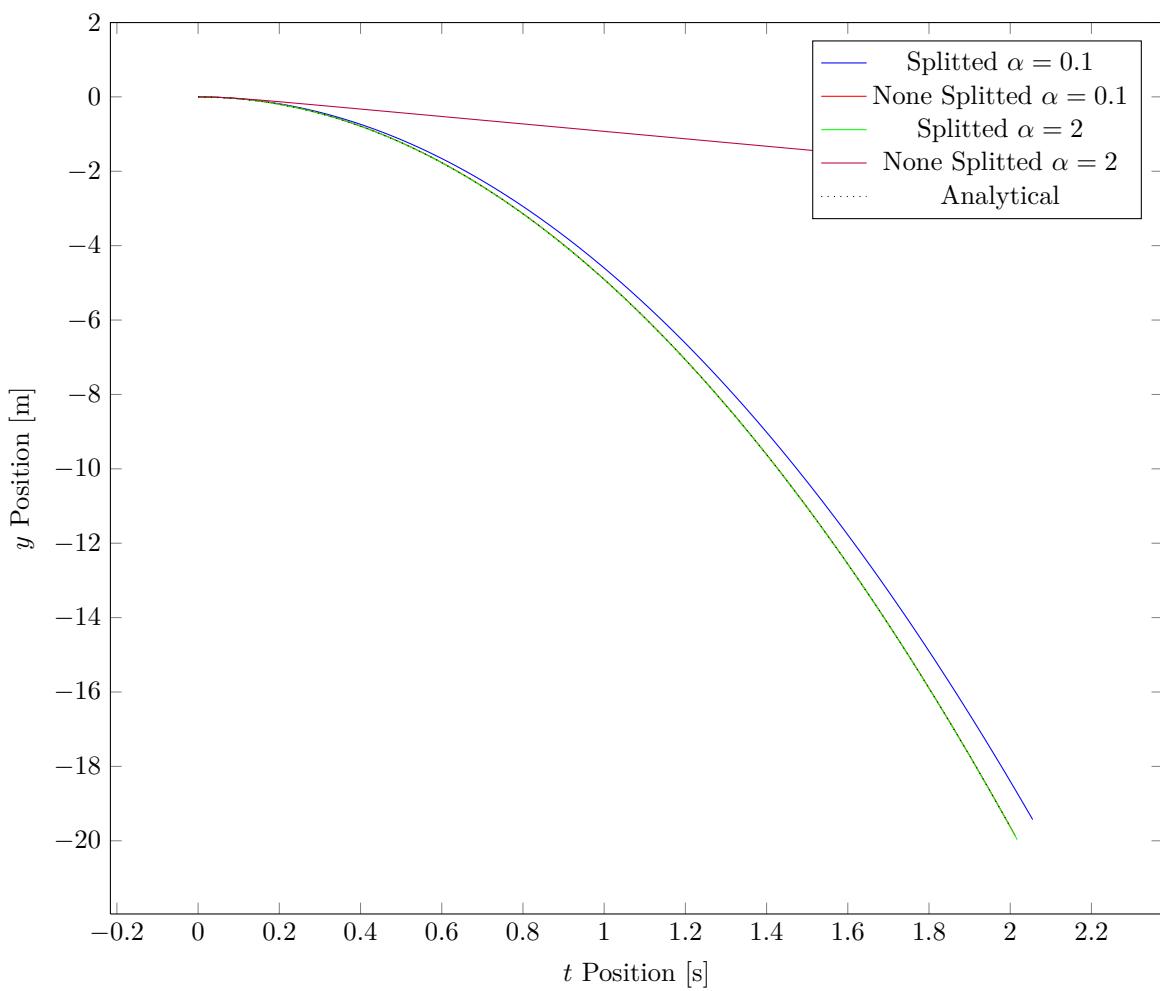

Figure 4.7: Comparison between splitting and not splitting for a single particle problem. The integration method is Runge-Kutta of order 4 for the two case. We see that the none splitting method (— and —) is a very good approximation to the analytical solution (····). Instead the splitting method (— and —) is different than the analytical solution (····). For the two methods, we have used $\Delta x = 0.01$. The time step limiter was a maximal time step $dt_{max} = 0.01$.

condition.

A single particle with initial x speed v_0 which go from y position y_0 and with initial time t_0 .

The speed is:

$$v_x = v_0 \quad (4.123)$$

$$v_y = -\frac{g}{2}(t - t_0)^2 \quad (4.124)$$

The position of the particle is then:

$$x = v_0(t - t_0) \quad (4.125)$$

$$y = y_0 - \frac{g}{2}(t - t_0)^2 \quad (4.126)$$

We will now try to define the speed in a particle manner. The time is given by:

$$t - t_0 = \frac{x}{v_0} \quad (4.127)$$

The speed is then given by:

$$v_x = v_0 \quad (4.128)$$

$$v_y = -\frac{g}{2} \frac{x^2}{v_0^2} \quad (4.129)$$

This is divergence free. So we are a solution of the Navier-Stokes equation.

But we doesn't respect the boundary condition.

We cannot know apriori if the numerical solution with correct boundary condition will respect this solution. But we can expect that a perturbation at boundary that will respect the boundary condition, will rest in the boundary and not enter in the fluid. This approximation is called Boundary Layer.

Result

For the numerical method, we have added a small perturbation in the initial x speed.

We see in figure 4.8, 4.10 and 4.12 that lateral speed are smirred by the viscosity and is quasi constant which is the analytical solution.

The boundary of the analytical solution is near to the numerical solution. Only the end of the fluid don't follow the analytical solution. This indicate that boundary layer is a correct approximation.

4.6.3 Jet

We now try to simulate the same problem than the lateral jet but in the same direction of gravity. We have no analytical solution in this case because the trivial particle solution is no more divergence free. Pressure is needed to push the fluid up.

We have done two final numerical run of this problem. All numerical run were done with 50 cells at basis. With a spacing of 0.0002 m. The viscosity is $\nu = 1.307 \cdot 10^{-6}$ Pas which is the viscosity of water. We use $\alpha = 0.5$. We use non splitted rk4 integration method. Particles which go below the 0 altitude are supressed.

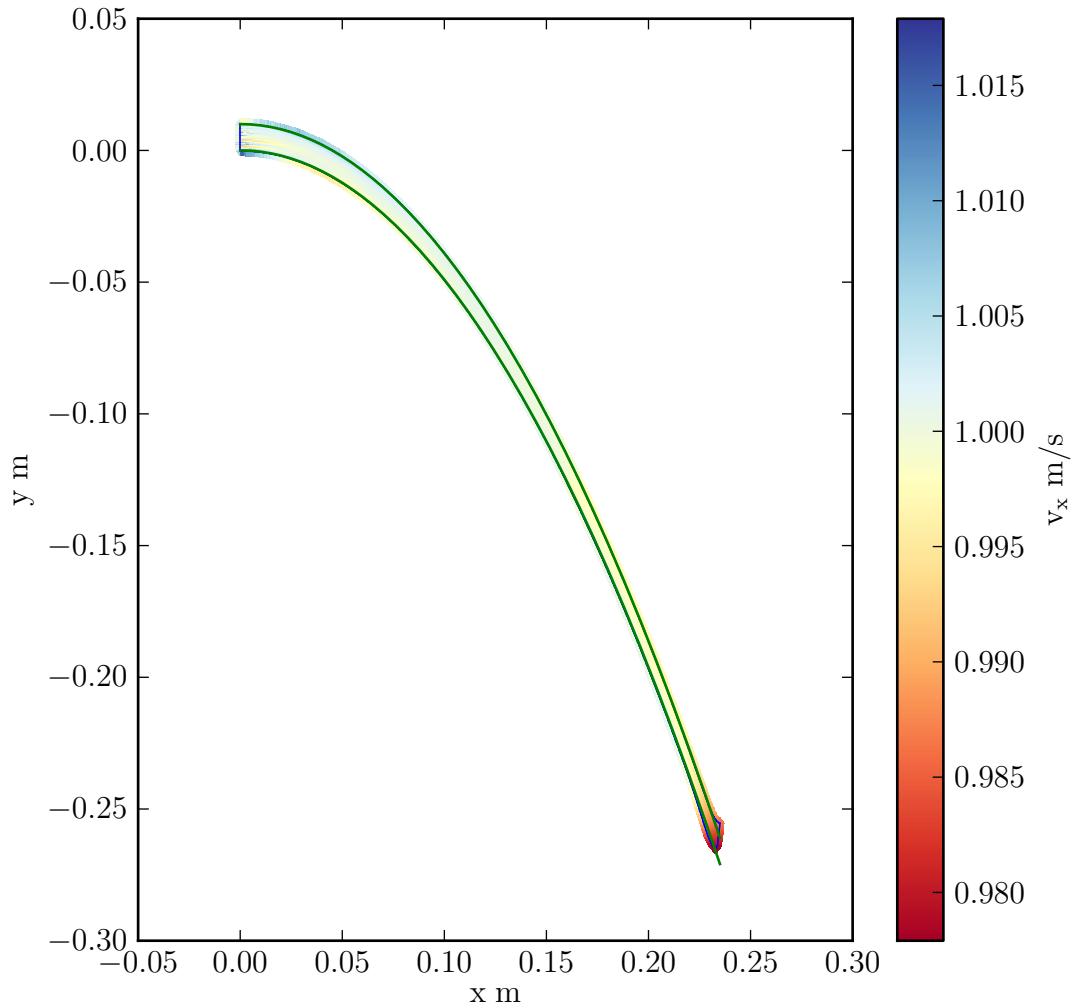

Figure 4.8: Non splitted result with Runge-Kutta rk4 with $\nu = 1.307e-6$, $\alpha = 0.5$. This is the x speed. The green line is the analytical solution boundary for the result without boundary condition. The blue line is the calculate boundary. We see that except at the end, the two coincide. At interior the speed take the analytical value which is constant and has a little jump in the boundary. The perturbation at initial condition are smirred by the viscosity.

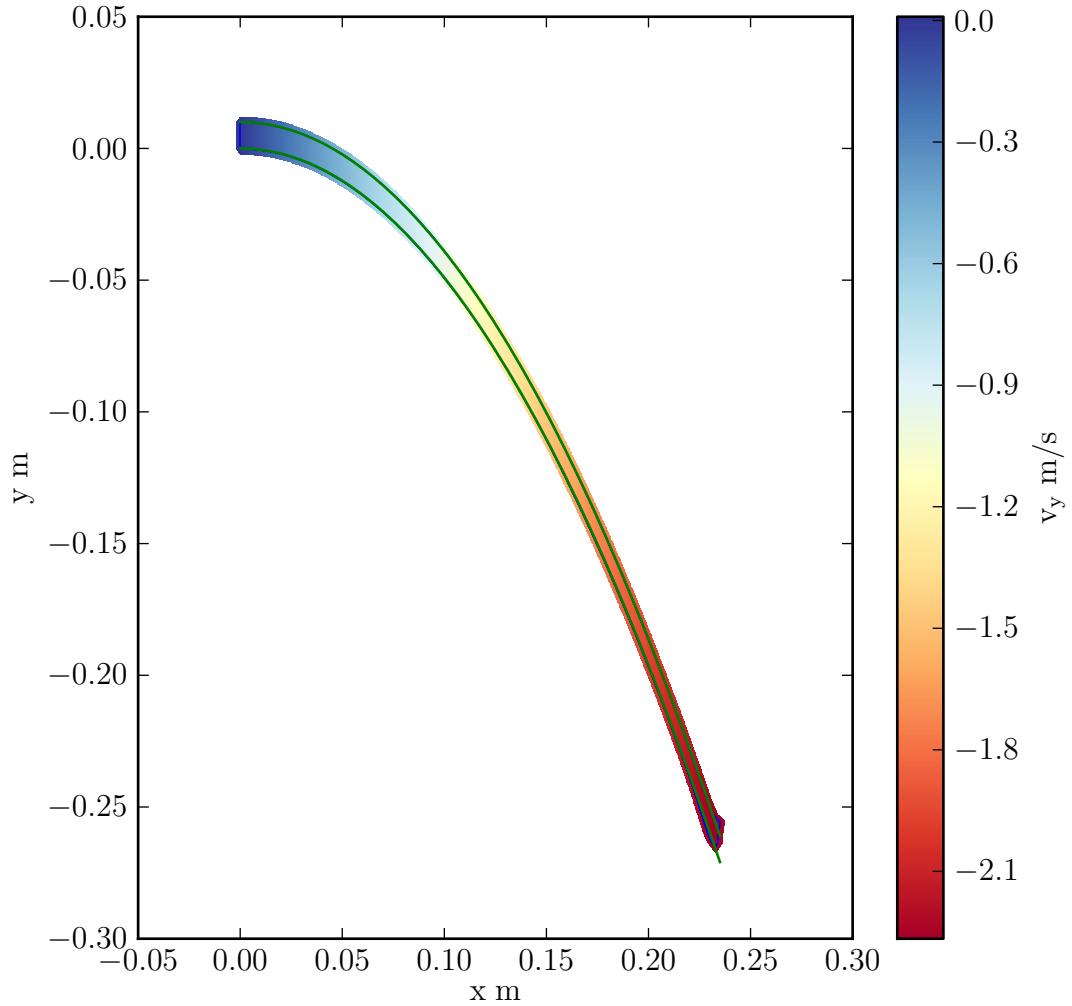

Figure 4.9: Non splitted result with Runge-Kutta rk4 with $\nu = 1.307e - 6$, $\alpha = 0.5$. This is the y speed. The green line is the analytical solution boundary for the result without boundary condition. The blue line is the calculate boundary. We see that except at the end, the two coincide. The y speed is proportional to the x^2 position, which coincide with the analytical result. The perturbation at initial condition are smirred by the viscosity.

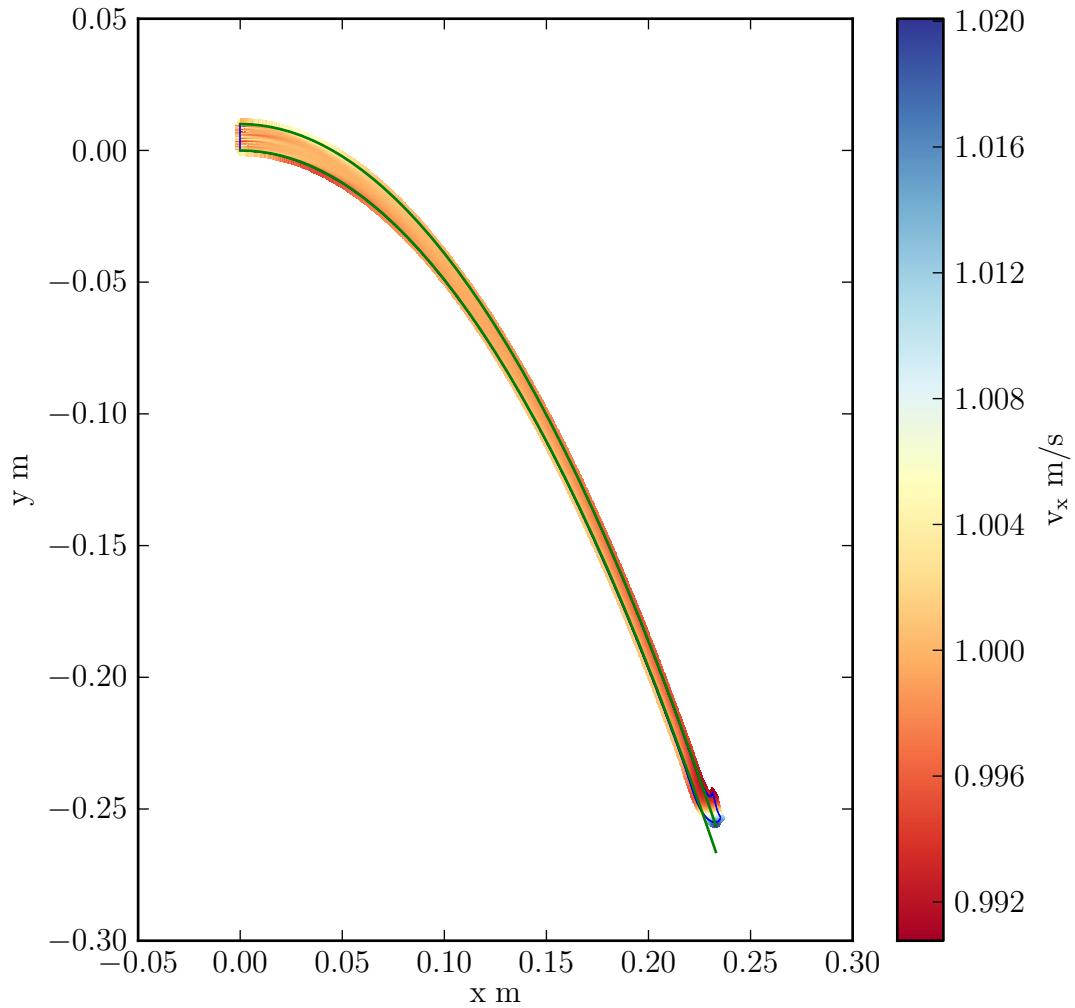

Figure 4.10: Splitted result with Runge-Kutta rk4 with $\nu = 1.307e - 6$, $\alpha = 0.5$. This is the x speed. The green line is the analytical solution boundary for the result without boundary condition. The blue line is the calculate boundary. We see that except at the end, the two coincide. At interior the speed take the analytical value which is constant and has a little jump in the boundary. The perturbation at initial condition are smirred by the viscosity.

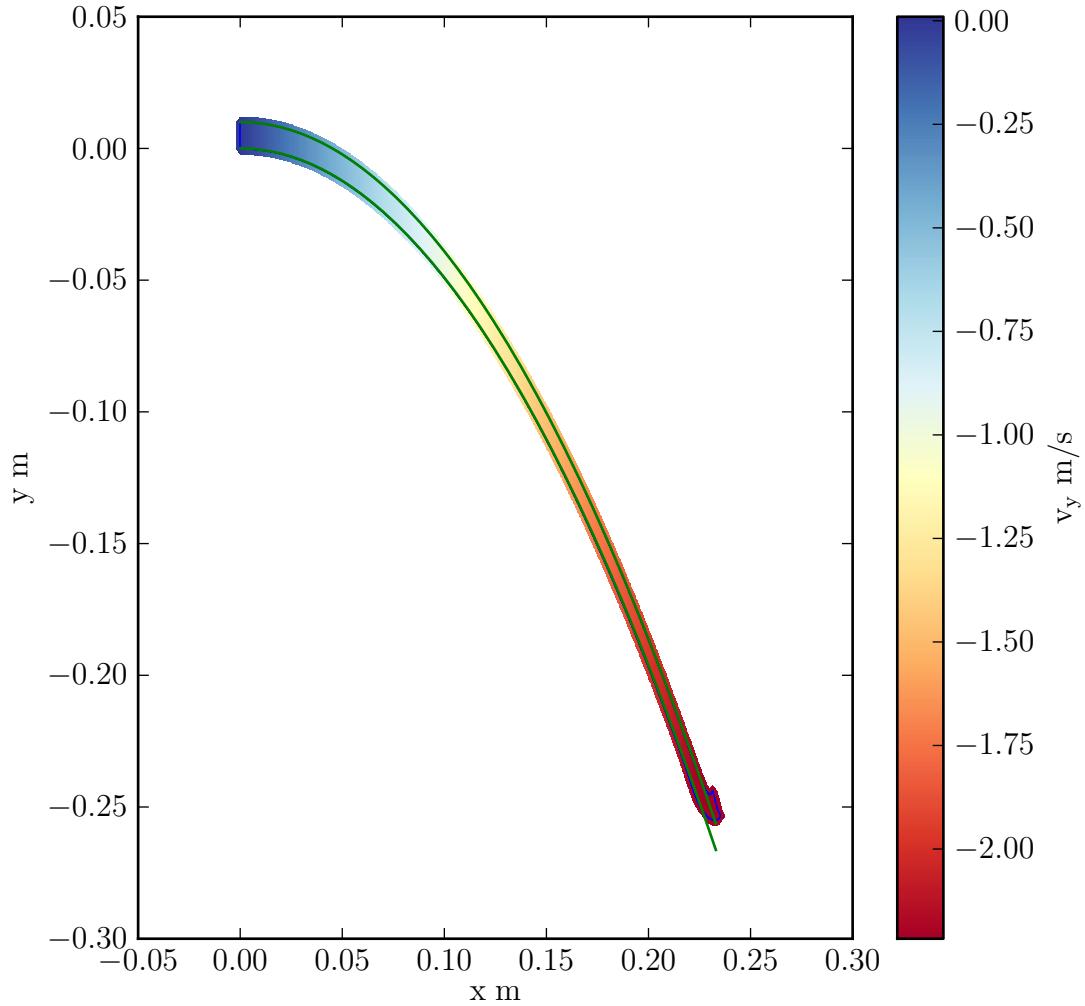

Figure 4.11: Splitted result with Runge-Kutta rk4 with $\nu = 1.307e-6$, $\alpha = 0.5$. This is the y speed. The green line is the analytical solution boundary for the result without boundary condition. The blue line is the calculate boundary. We see that except at the end, the two coincide. The y speed is proportional to the x^2 position, which coincide with the analytical result. The perturbation at initial condition are smirred by the viscosity.

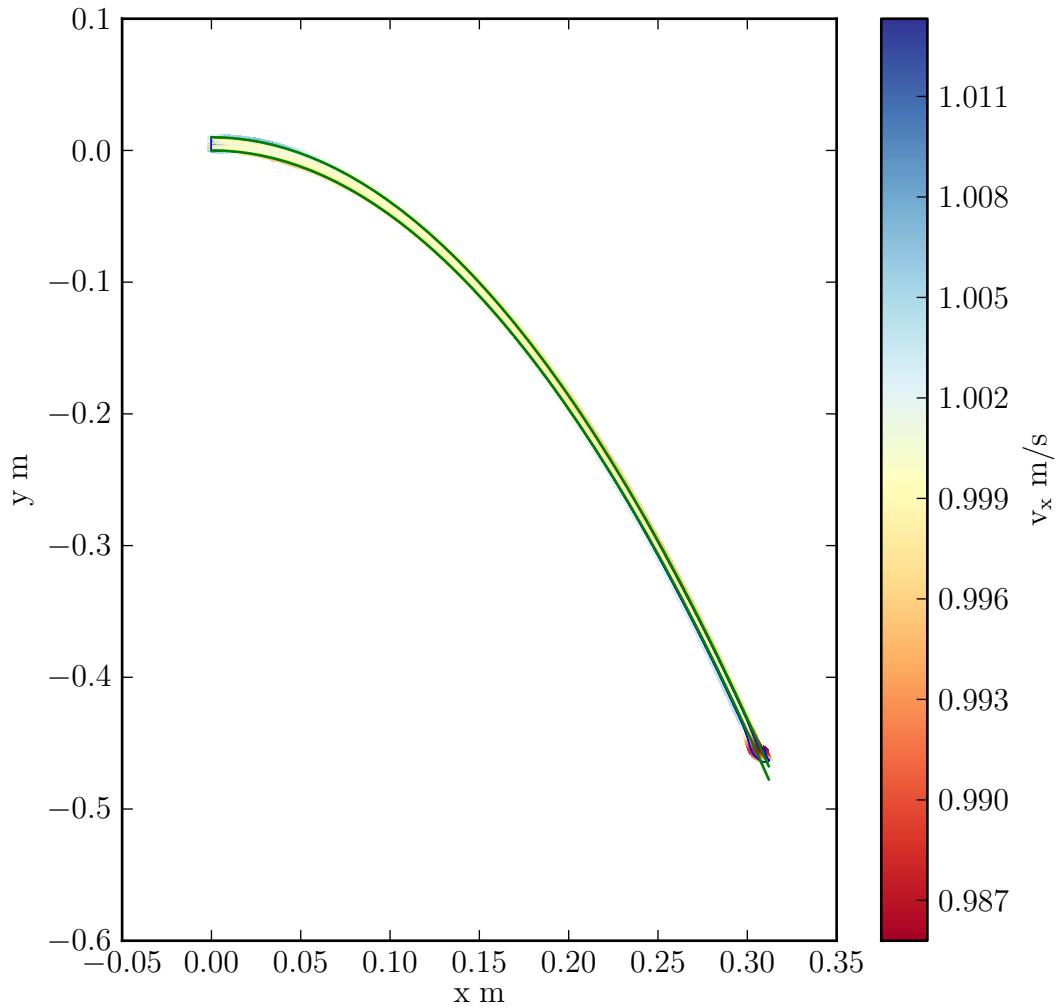

Figure 4.12: Splitted result with Euler with $\nu = 1.307e - 6$, $\alpha = 0.5$. This is the x speed. The green line is the analytical solution boundary for the result without boundary condition. The blue line is the calculate boundary. We see that except at the end, the two coincide. At interior the speed take the analytical value which is constant and has a little jump in the boundary. The perturbation at initial condition are smirred by the viscosity.

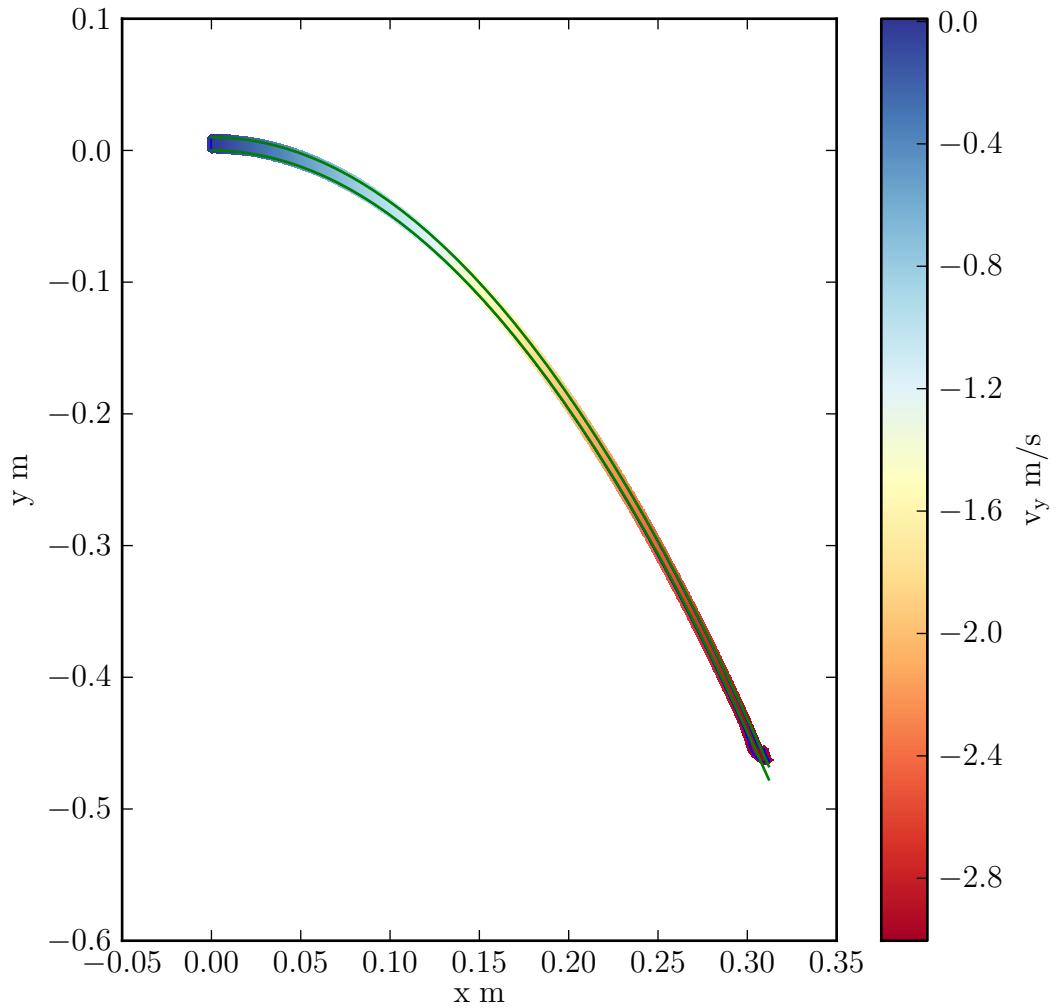

Figure 4.13: Splitted result with Euler with $\nu = 1.307e - 6$, $\alpha = 0.5$. This is the y speed. The green line is the analytical solution boundary for the result without boundary condition. The blue line is the calculate boundary. We see that except at the end, the two coincide. The y speed is proportional to the x^2 position, which coincide with the analytical result. The perturbation at initial condition are smirred by the viscosity.

The two run took a day to complete. 3 dimmensional run was not possible for reason of time and computing power.

This is shown in figure 4.14, 4.15, 4.16, 4.17, 4.18 and 4.19.

The most expensive operation is to calculate the projection operator for every iteration.

We see three phase in the computed result:

1. Vertical motion without deformation. Gravity had not the time to act a lot on the speed.
2. The top particle want to push the below particles because of gravity. But because of incompressibility the below region become larger. This generate a lateral speed.
3. We touch the supression particles limit and have now a stationary state.

We think that the reason why the jet lateral distance is so big, is because we are in a 2d problem where we have less spatial liberty. The pression exerced by the gravity can in 2d escape only in one dimension and not two.

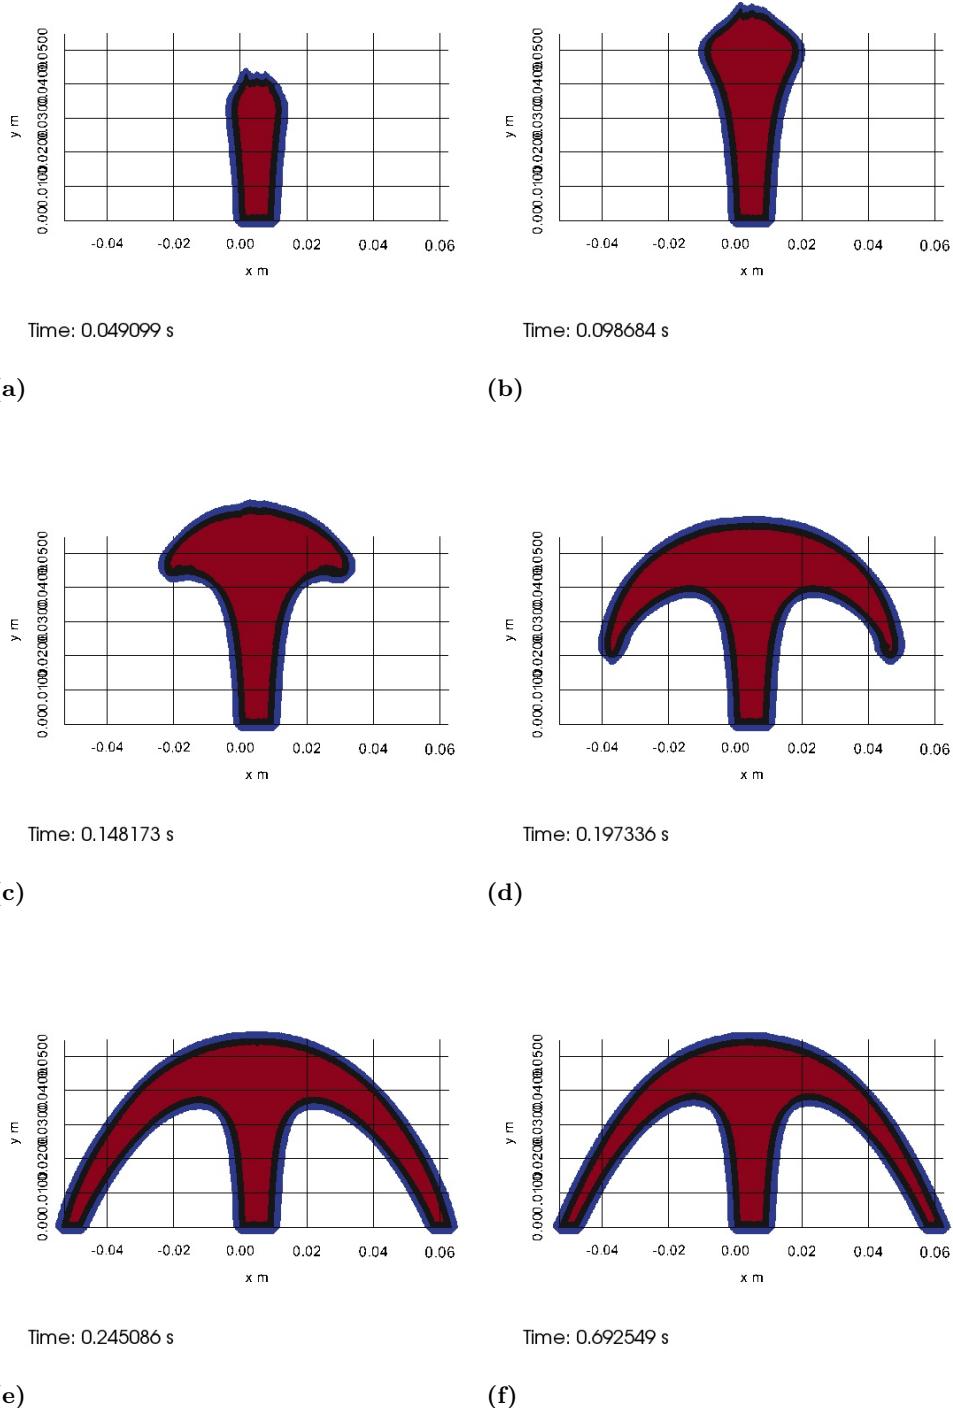

Figure 4.17: Jet simulation with an initial speed 1 m/s. The black surface are in fact the particles.

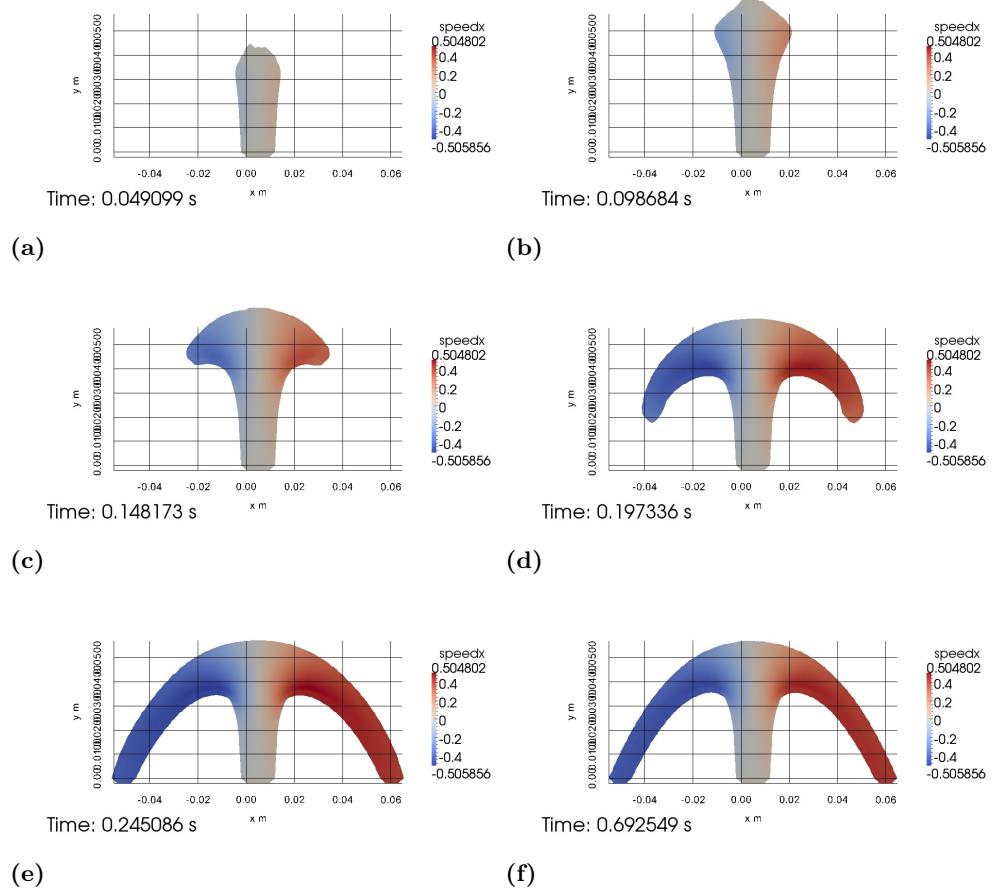

Figure 4.18: Jet simulation with an initial speed 1 m/s. This is the representation of speed in the x direction.

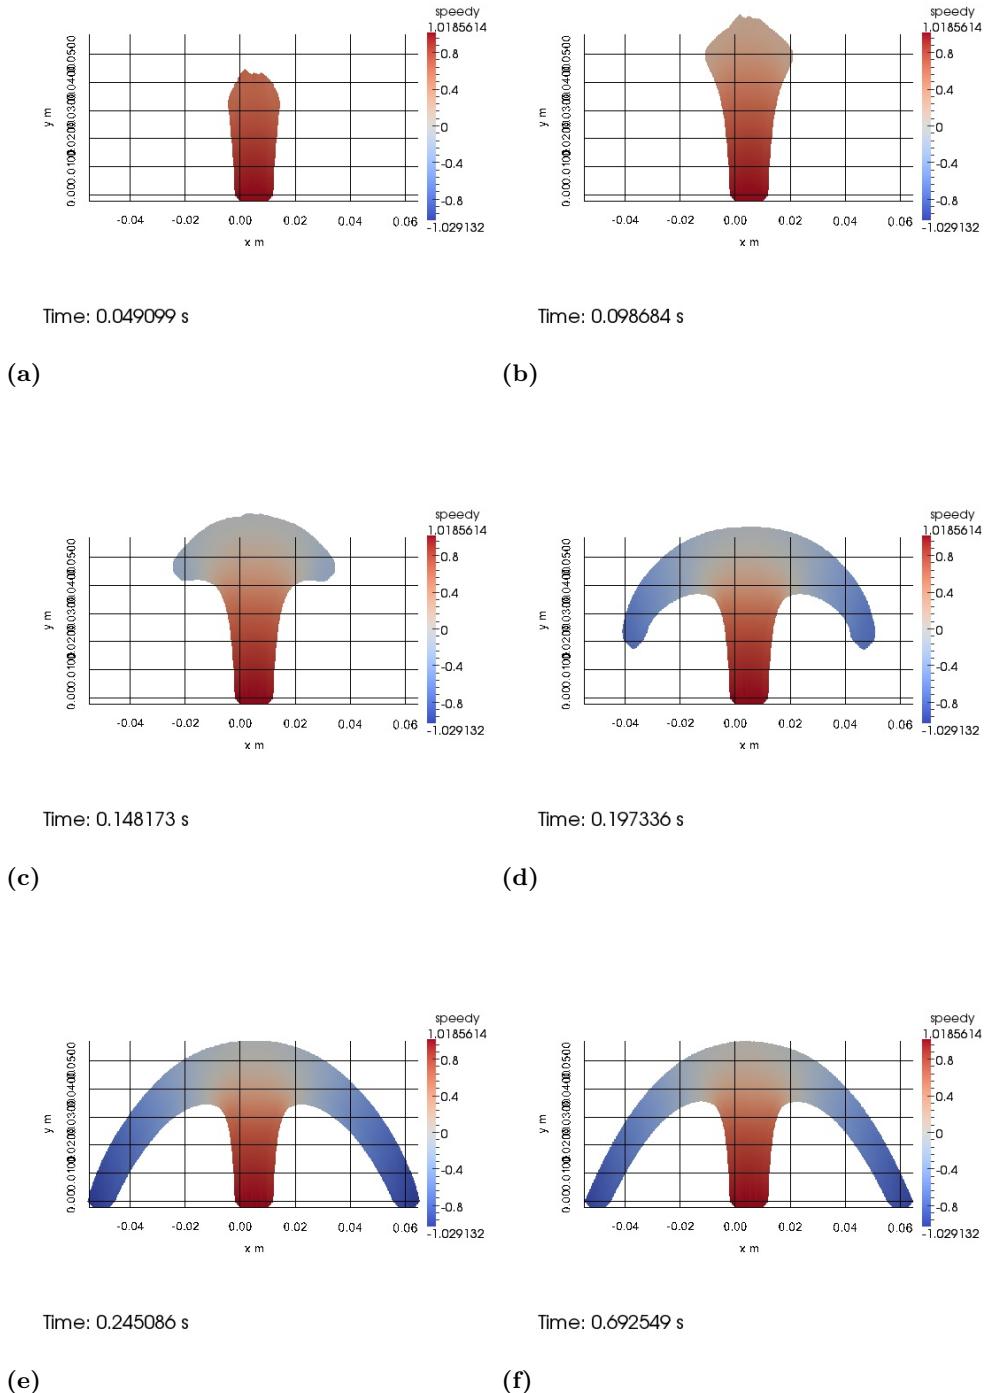

Figure 4.19: Jet simulation with an initial speed 1 m/s. This is the representation of speed in the y direction.

Chapter 5

Conclusion

In conclusion we were able to have a “simple” scheme to solve free surface incompressible Navier-Stokes equations. For this we have used the following elements:

- A spatial discretization on a staggered grid and definition of differential operator on it.
- The reduction of the original problem to an ODE with a projected function. This need to solve a linear system at every time step.
- A topological marker particle and interpolation method on the marker.
- An extrapolation operator that need to ensure boundary conditions.

We were not able to launch 3d run and are aware of the high numerical cost of direct Navier-Stokes methods for small viscosity problem, but judged that it was the better method to begin with.

5.1 Possible improvement

The following theoretical improvement are possible:

- Use higher order spatial discretization.
- Use other topological marker instead of particle like level set or boundary surface representation.
- Have better discretization at free surface boundary.
- Have a variant of Runge-Kutta method that are correct if we have Dirac delta in the function or use smooth topological change.

The following code improvement are possible:

- Have a linear solver which can use the fact that topology doesn’t change much between iteration to be faster in average.
- Make the code run on parallel on cpu and gpu.

5.2 Software used

The code was written primary in **C++11**. The final version use the following library:

- Umfpack as linear solver.
- VTK for output in the vtk format used in the visualization software Paraview.

Previous version used:

- Boost library for python binding and externalization.
- Pyamg in python for multigrid.
- VianaCl for multigrid.
- Lusol in fortran for sparse Lu updating.
- Spooles as linear solver.
- ...

For postprocessing and generate this document the following software were used:

- Lua^LA_TE_X as L_AT_EX program with some lua script to generate picture.
- Pgfpplots and tikz for picture and graphics.
- Matplotlib in python to generate picture and graphics.
- Paraview to visualize the data.

For debugging of the **C++11** code in addition to GDB, Valgrind was used to track memory related error and memory leak.

5.3 Thanks

I am very thankfull to:

Prof. Martin Gander: for the supervising of the work and all my numerical analysis knowledge.

Dr. Félix Kwok: for the supervising of the work and contact in pratical numerical analysis.

Prof. Peter Wittwer: for the Mathematics and Physics courses in my Physics studies.

My family: Reto, Norma, Roland, Tamara: for supporting me and all the fun together. And for proof reading.
